All About...

the Foreign Exchange Market
in the United States

By Sam Y. Cross

Federal Reserve Bank of New York

1998
FOREWORD

Over the past forty years, the Federal Reserve Bank of New York has published monographs about the operation of the foreign exchange market in the United States. The first of these reports, The New York Foreign Exchange Market, by Alan Holmes, was published in 1959. The second, also entitled The New York Foreign Exchange Market, was written by Alan Holmes and Francis Schott and published in 1965. The third publication, Foreign Exchange Markets in the United States, was written by Roger Kubarych and published in 1978.

Each of these publications presents a lucid and informed picture of the foreign exchange market and how it operates, filled with rich insights and reflecting a profound understanding of the market and its complex mechanisms. Roger Kubarych’s report, written twenty years ago, provided a valuable analysis of the foreign exchange market that is still read and widely appreciated by persons interested in gaining a deeper understanding of that market.

But the foreign exchange market is always changing, always adapting to a shifting world economy and financial environment. The metamorphosis of the 1980s and ’90s in both finance and technology has changed the structure of the market and its operations in profound ways. It is useful to reexamine the foreign exchange market from today’s perspective.

The focus of the present book is once again on the U.S. segment of the global foreign exchange market. Chapters 1-3 describe the structure of the market and how it has changed. Chapters 4-6 comment on the main participant groups and the instruments that are traded. Chapters 7-8 look at foreign exchange trading from a micro, rather than macro, point of view—how an individual bank or other dealing firm sees things. Chapters 9-11 comment on some of the broader issues facing the international monetary system and how governments, central banks, and market participants operate within that system. This is followed by an epilogue, emphasizing that there are many unanswered questions, and that we can expect many further changes in the period ahead, changes that we cannot now easily predict.

Markets go back a long time—in English law, the concept was recognized as early as the 11th century—and it is interesting to compare today’s foreign exchange market with historical concepts. More than one hundred years ago, Alfred Marshall wrote that “a perfect market is a district, small or large, in which there are many buyers and many sellers, all so keenly on the alert and so well acquainted in one another’s affairs that the price of a commodity is always practically the same for the whole of the district.”
Today’s over-the-counter global market in foreign exchange meets many of the standards that classical economists expected of a smoothly functioning and effective market. There are many buyers and many sellers. Entry by new participants is generally not too difficult. The over-the-counter market is certainly not confined to a single geographical area as the classical standards required. However, with the advance of technology, information is dispersed quickly and efficiently around the globe, with vast amounts of information on political and economic developments affecting exchange rates. As in commodity markets, identical products are being traded in financial centers all around the world. Essentially, the same marks, dollars, francs, and other currencies are being bought and sold, no matter where the purchase takes place. Traders in different centers are continuously in touch and buying and selling from each other. With trading centers open at the same time, there is no evidence of substantial price differences lasting more than momentarily.

Not all features of today’s over-the-counter market fully conform to the classical ideals. There is not perfect “transparency,” or full and immediate disclosure of all trading activity. Individual traders know about the orders and the flow of trading activity in their own firms, but that information may not be known to everyone else in the market. However, transparency has increased enormously in recent years. With the growth of electronic dealing systems and electronic brokering systems, the price discovery process has become less exclusive and pricing information more broadly disseminated—at least for certain foreign exchange products and currency pairs. Indeed, by most measures, the over-the-counter foreign exchange market is regarded by observers as not only extremely large and liquid, but also efficient and smoothly functioning.

Many persons, both within and outside the Federal Reserve, helped in the preparation of this book, through advice, criticism, and drafting. In the Federal Reserve, first and foremost, before his tragic death, Akbar Akhtar was a close collaborator on the project over an extended period, contributing to all aspects of the effort and helping to produce much of what is here. Dino Kos and his colleagues in the Markets Group were exceedingly helpful. Allan Malz contributed in many important ways. Robin Bensignor, John Kambhu, and Steven Malin also provided much valuable assistance, and Ed Steinberg’s contribution as editor was invaluable. At the Federal Reserve Board, Ralph Smith offered very useful suggestions and comments.

Outside of the Federal Reserve, Michael Paulus of Bank of America contributed profoundly and in many ways to the entire project, both in technical matters and on questions of broader philosophy. Christine Kwon also assisted generously. Members of the trading room staff at Morgan Guaranty were also very helpful. At Fuji Bank, staff officials provided valuable assistance. Richard Levich provided very helpful comments.
### Chapters

#### Foreword

1. How the Global Environment Has Changed

1. How Foreign Exchange Turnover Has Grown

#### Two: Some Basic Concepts: Foreign Exchange, the Foreign Exchange Rate, Payment and Settlement Systems ➤ p. 9

1. Why We Need Foreign Exchange
2. What "Foreign Exchange" Means
3. Role of the Exchange Rate
   - Bilateral and Trade-Weighted Exchange Rates
4. Payment and Settlement Systems
   - Payments via Fedwire and CHIPS

#### Three: Structure of the Foreign Exchange Market ➤ p. 15

1. It Is the World's Largest Market
2. It Is a Twenty-Four Hour Market
4. The Market's Most Widely Traded Currency Is the Dollar
5. It Is an "Over-the-Counter" Market With an "Exchange-Traded" Segment

#### Four: The Main Participants in the Market ➤ p. 23

1. Foreign Exchange Dealers
2. Financial and Nonfinancial Customers
3. Central Banks
   - Classification of Exchange Rate Arrangements, September 1997
4. Brokers
   - In the Over-the-Counter Market
   - Voice Brokers
   - Automated Order-Matching or Electronic Broking Systems
   - In the Exchange-Traded Market

#### Five: Main Instruments: Over-the-Counter Market ➤ p. 31

1. Spot
   - There Is a Buying Price and a Selling Price
   - How Spot Rates Are Quoted: Direct and Indirect Quotes, European and American Terms
   - There Is a Base Currency and a Terms Currency
   - Bids and Offers Are for the Base Currency
   - Quotes Are in Basis Points
   - Cross Rate Trading
   - Deriving Cross Rates From Dollar Exchange Rates
2. Outright Forwards
   - Relationship of Forward to Spot—Covered Interest Rate Parity
   - Role of the Offshore Deposit Markets for Euro-Dollars and Other Currencies
   - How Forward Rates Are Quoted by Traders
   - Calculating Forward Premium/Discount Points
   - Non-Deliverable Forwards (NDFs)

Since the early 1970s, with increasing internationalization of financial transactions, the foreign exchange market has been profoundly transformed, not only in size, but in coverage, architecture, and mode of operation. That transformation is the result of structural shifts in the world economy and in the international financial system. Among the major developments that have occurred in the global financial environment are the following:

- A basic change in the international monetary system, from the fixed exchange rate “par value” requirements of Bretton Woods that existed until the early 1970s to the flexible legal structure of today, in which nations can choose to float their exchange rates or to follow other exchange rate regimes and practices of their choice.

- A tidal wave of financial deregulation throughout the world, with massive elimination of government controls and restrictions in nearly all countries, resulting in greater freedom for national and international financial transactions, and in greatly increased competition among financial institutions, both within and across national borders.

- A fundamental move toward institutionalization and internationalization of savings and investment, with funds managers and institutions around the globe having vastly larger sums available, which they are investing and diversifying across borders and currencies in novel ways and in ever larger amounts as they seek to maximize returns.

- A broadening and deepening trend toward international trade liberalization, within a framework of multilateral trade agreements, such as the Tokyo and the Uruguay Rounds of the General Agreement on Tariffs and Trade, the North American Free Trade Agreement, and U.S. bilateral trade initiatives with China, Japan, and the European Union.
In 1998, the Federal Reserve's most recently published survey of reporting dealers in the United States estimated that foreign exchange turnover in the U.S. market was $351 billion a day, after adjustments for double counting. That total is an increase of 43% above the estimated turnover in 1995 and more than 60 times the turnover in 1977, the first year for which roughly comparable survey data are available.
In some ways, this estimate understates the growth and the present size of the U.S. foreign exchange market. The $351 billion estimated daily turnover covered only the three traditional instruments in the “over-the-counter” (OTC) market—spot, outright forwards, and foreign exchange (FX) swaps; it did not include over-the-counter currency options and currency swaps traded in the OTC market, which totaled about $32 billion a day in notional value (or face value) in 1998. Nor did it include the two products traded, not “over-the-counter,” but in organized exchanges—currency futures and exchange-traded currency options, for which the notional value of the turnover was perhaps $10 billion per day.1

The global foreign exchange market also has shown phenomenal growth. In 1998, in a survey under the auspices of the Bank for International Settlements (BIS), global turnover of reporting dealers was estimated at about $1.49 trillion per day for the traditional products, plus an additional $97 billion for over-the-counter currency options and currency swaps, and a further $12 billion for currency instruments traded on the organized exchanges. In the traditional products, global foreign exchange turnover, measured in current exchange rates, increased by more than 80 percent between 1992 and 1998.

The expansion in foreign exchange turnover, in the United States and globally, reflects the continuing growth of international trade and the prodigious expansion in global finance and investment during recent years. With respect to trade, the dollar value of United States international transactions in goods and services—the sum of exports and imports—tripled between 1980 and 1995 to around 15 times its 1970 level. International trade in the global economy also has expanded at a rapid pace. World merchandise trade is now more than 2½ times its 1980 level (Figure 1-1).
But international trade cannot account for the huge increase in the U.S. foreign exchange turnover over the past twenty-five years. The enormous expansion of international capital transactions, both here and abroad, has been a dominant force. U.S. international capital inflows, including sales of U.S. bonds and equities to foreigners, acquisition of U.S. factories by foreigners, and bank deposit inflows, have averaged more than $180 billion per year since the mid-80s.

Large and persistent external trade and payments deficits in the United States and
corresponding surpluses abroad have contributed to the growth in financing. Through much of the period since 1983, the United States has recorded trade deficits in the range of $100-$200 billion per year, while Japan and, to a lesser extent, Germany have registered substantial trade surpluses. In contrast, all three countries experienced only modest trade deficits or surpluses through the 1960s and early 1970s.

The internationalization of financial activity has increased rapidly. Cross-border bank claims are now nearly five times the level of 15 years ago; as a percentage of the combined GDP of the OECD countries, these claims have risen from about 25 percent in 1980 to about 42 percent in 1995. During that same period, cross-border securities transactions in the three largest economies—United States, Japan, and Germany—expanded from less than 10 percent of GDP to around 70 percent of GDP in Japan and to well above 100 percent of GDP in Germany and the United States (Figure 1-2). Annual issuance of international bonds has more than quadrupled during the past ten years (Figure 1-2). Between 1988 and 1993, securities settlements through Euroclear and Cedel—the two main Euro market clearing houses—increased six-fold.

All of this provided fertile ground for growth in foreign exchange trading.
CHAPTER 2

1. WHY WE NEED FOREIGN EXCHANGE

Almost every nation has its own national currency or monetary unit—its dollar, its peso, its rupee—used for making and receiving payments within its own borders. But foreign currencies are usually needed for payments across national borders. Thus, in any nation whose residents conduct business abroad or engage in financial transactions with persons in other countries, there must be a mechanism for providing access to foreign currencies, so that payments can be made in a form acceptable to foreigners. In other words, there is need for “foreign exchange” transactions—exchanges of one currency for another.

2. WHAT “FOREIGN EXCHANGE” MEANS

“Foreign exchange” refers to money denominated in the currency of another nation or group of nations. Any person who exchanges money denominated in his own nation’s currency for money denominated in another nation’s currency acquires foreign exchange. That holds true whether the amount of the transaction is equal to a few dollars or to billions of dollars; whether the person involved is a tourist cashing a traveler’s check in a restaurant abroad or an investor exchanging hundreds of millions of dollars for the acquisition of a foreign company; and whether the form of money being acquired is foreign currency notes, foreign currency-denominated bank deposits, or other short-term claims denominated in foreign currency. A foreign exchange transaction is still a shift of funds, or short-term financial claims, from one country and currency to another.

Thus, within the United States, any money denominated in any currency other than the U.S. dollar is, broadly speaking, “foreign exchange.”

Foreign exchange can be cash, funds available on credit cards and debit cards, traveler’s checks, bank deposits, or other short-term claims. It is still “foreign exchange” if it is a short-term negotiable financial claim denominated in a currency other than the U.S. dollar.

But, in the foreign exchange market described in this book—the international network of major foreign exchange dealers engaged in high-volume trading around the world—foreign exchange transactions almost always take the form of an exchange of bank deposits of different national currency denominations. If one bank agrees to sell dollars for Deutsche marks to another bank, there will be an exchange between the two parties of a dollar bank deposit for a DEM bank deposit. In this book, “foreign exchange” means a bank balance denominated in a foreign (non-U.S. dollar) currency.

3. ROLE OF THE EXCHANGE RATE

The exchange rate is a price—the number of units of one nation’s currency that must be surrendered in order to acquire one unit of another nation’s currency. There are scores of “exchange rates” for the U.S. dollar. In the spot market, there is an exchange rate for every other national currency.
traded in that market, as well as for various composite currencies or constructed monetary units such as the International Monetary Fund’s “SDR,” the European Monetary Union’s “ECU,” and beginning in 1999, the “euro.” There are also various “trade-weighted” or “effective” rates designed to show a currency’s movements against an average of various other currencies (see Box 2-1). Quite apart from the spot rates, there are additional exchange rates for other delivery dates, in the forward markets. Accordingly, although we talk about the dollar exchange rate in

**BOX 2-1**

**BILATERAL AND TRADE-WEIGHTED EXCHANGE RATES**

Market trading is bilateral, and spot and forward market exchange rates are quoted in bilateral terms—the dollar versus the pound, franc, or peso. Changes in the dollar’s average value on a multilateral basis—(i.e., its value against a group or basket of currencies) are measured by using various statistical indexes that have been constructed to capture the dollar’s movements on a trade-weighted average, or effective exchange rate basis. Among others, the staff of the Federal Reserve Board of Governors has developed and regularly publishes such indexes, which measure the average value of the dollar against the currencies of both a narrow group and a broad group of other countries. Such trade-weighted and other indexes are not traded in the OTC spot or forward markets, where only the constituent currencies are traded. However, it is possible to buy and sell certain dollar index based futures and exchange-traded options in the exchange-traded market.

the market, and it is useful to do so, there is no single, or unique dollar exchange rate in the market, just as there is no unique dollar interest rate in the market.

A market price is determined by the interaction of buyers and sellers in that market, and a market exchange rate between two currencies is determined by the interaction of the official and private participants in the foreign exchange rate market. For a currency with an exchange rate that is fixed, or set by the monetary authorities, the central bank or another official body is a key participant in the market, standing ready to buy or sell the currency as necessary to maintain the authorized pegged rate or range. But in the United States, where the authorities do not intervene in the foreign exchange market on a continuous basis to influence the exchange rate, market participation is made up of individuals, nonfinancial firms, banks, official bodies, and other private institutions from all over the world that are buying and selling dollars at that particular time.

The participants in the foreign exchange market are thus a heterogeneous group. Some of the buyers and sellers may be involved in the “goods” market, conducting international transactions for the purchase or sale of merchandise. Some may be engaged in “direct investment” in plant and equipment, or in “portfolio investment,” dealing across borders in stocks and bonds and other financial assets, while others may be in the “money market,” trading short-term debt instruments internationally. The various investors, hedgers, and speculators may be focused on any time period, from a few minutes to several years. But, whether official or private, and whether their motive be investing, hedging, speculating, arbitraging, paying for imports, or seeking to influence the rate, they are all part of the aggregate demand for and supply
of the currencies involved, and they all play a role in determining the market exchange rate at that instant.

Given the diverse views, interests, and time frames of the participants, predicting the future course of exchange rates is a particularly complex and uncertain business. At the same time, since the exchange rate influences such a vast array of participants and business decisions, it is a pervasive and singularly important price in an open economy, influencing consumer prices, investment decisions, interest rates, economic growth, the location of industry, and much else. The role of the foreign exchange market in the determination of that price is critically important.

### 4. PAYMENT AND SETTLEMENT SYSTEMS

Just as each nation has its own national currency, so also does each nation have its own payment and settlement system—that is, its own set of institutions and legally acceptable arrangements for making payments and executing financial transactions within that country, using its national currency. “Payment” is the transmission of an instruction to transfer value that results from a transaction in the economy, and “settlement” is the final and unconditional transfer of the value specified in a payment instruction. Thus, if a customer pays a department store bill by check, “payment” occurs when the check is placed in the hands of the department store, and “settlement” occurs when the check clears and the department store’s bank account is credited. If the customer pays the bill with cash, payment and settlement are simultaneous.

When two traders enter a deal and agree to undertake a foreign exchange transaction, they are agreeing on the terms of a currency exchange and committing the resources of their respective institutions to that agreement. But the execution of that exchange—the settlement—does not take place until later.

Executing a foreign exchange transaction requires two transfers of money value, in opposite directions, since it involves the exchange of one national currency for another. Execution of the transaction engages the payment and settlement systems of both nations, and those systems play a key role in the operations of the foreign exchange market.

Payment systems have evolved and grown more sophisticated over time. At present, various forms of payment are legally acceptable in the United States—payments can be made, for example, by cash, check, automated clearinghouse (a mechanism developed as a substitute for certain forms of paper payments), and electronic funds transfer (for large value transfers between banks). Each of these accepted forms of payment has its own settlement techniques and arrangements.

By number of transactions, most payments in the United States are still made with cash (currency and coin) or checks. However, the electronic funds transfer systems, which account for less than 0.1 percent of the number of all payments transactions in the United States, account for more than 80 percent of the value of payments. Thus,
electronic funds transfer systems represent a key and indispensable component of the payment and settlement systems. It is the electronic funds transfer systems that execute the inter-bank transfers between dealers in the foreign exchange market. The two electronic funds transfer systems operating in the United States are CHIPS (Clearing House Interbank Payments System), a privately owned system run by the New York Clearing House, and Fedwire, a system run by the Federal Reserve (see Box 2-2).

Other countries also have large-value interbank funds transfer systems, similar to Fedwire and CHIPS in the United States. In the United Kingdom, the pound sterling leg of a foreign exchange transaction is likely to be settled through CHAPS—the Clearing House Association Payments System, an RTGS system whose member banks settle with each other through their accounts at the Bank of England. In Germany, the Deutsche mark leg of a transaction is settled through EAF—an electronic payments system where settlements are made through accounts at Germany's central bank, the Deutsche Bundesbank. A new payment system, named Target, has been designed to link RTGS systems within the European Community, to enable participants to handle transactions in the euro upon its introduction on January 1, 1999.

Globally, more than 80 percent of global foreign exchange transactions have a dollar leg. Thus, the amount of daily dollar settlements is huge, one trillion dollars per day or more. The settlement of foreign exchange transactions accounts for the bulk of total dollar payments processed through CHIPS each day.

The matter of settlement practices is of particular importance to the foreign exchange market.
market because of “settlement risk,” the risk that one party to a foreign exchange transaction will pay out the currency it is selling but not receive the currency it is buying. Because of time zone differences and delays caused by the banks’ own internal procedures and corresponding banking arrangements, a substantial amount of time can pass between a payment and the time the counter-payment is received—and a substantial credit risk can arise. Efforts to reduce or eliminate settlement risk are discussed in Chapter 8.
The foreign exchange market is by far the largest and most liquid market in the world. The estimated worldwide turnover of reporting dealers, at around $1½ trillion a day, is several times the level of turnover in the U.S. Government securities market, the world’s second largest market. Turnover is equivalent to more than $200 in foreign exchange market transactions, every business day of the year, for every man, woman, and child on earth!

The breadth, depth, and liquidity of the market are truly impressive. Individual trades of $200 million to $500 million are not uncommon. Quoted prices change as often as 20 times a minute. It has been estimated that the world’s most active exchange rates can change up to 18,000 times during a single day. Large trades can be made, yet econometric studies indicate that prices tend to move in relatively small increments, a sign of a smoothly functioning and liquid market.

While turnover of around $1½ trillion per day is a good indication of the level of activity and liquidity in the global foreign exchange market, it is not necessarily a useful measure of other forces in the world economy. Almost two-thirds of the total represents transactions among the reporting dealers themselves—with only one-third accounted for by their transactions with financial and non-financial customers. It is important to realize that an initial dealer transaction with a customer in the foreign exchange market often leads to multiple further transactions, sometimes over an extended period, as the dealer institutions readjust their own positions to hedge, manage, or offset the risks involved. The result is that the amount of trading in the interbank market often accounts for a very small share of that institution’s total foreign exchange activity.

Among the various financial centers around the world, the largest amount of foreign exchange trading takes place in the United Kingdom, even though that nation’s currency—the pound sterling—is less widely traded in the market than several others. As shown in Figure 3-1, the United Kingdom accounts for about 32 percent of the global total; the United States ranks a distant second with about 18 percent, and Japan is third with 8 percent. Thus, together, the three largest markets—one each in the European, Western Hemisphere, and Asian time zones—account for about 58 percent of global trading. After these three leaders comes Singapore with 7 percent.

![Shares of Reported Global Foreign Exchange Turnover, 1998](source: Bank for International Settlements. Note: Percent of total reporting foreign exchange turnover, adjusted for intra-country double-counting.)
During the past quarter century, the concept of a twenty-four hour market has become a reality. Somewhere on the planet, financial centers are open for business, and banks and other institutions are trading the dollar and other currencies, every hour of the day and night, aside from possible minor gaps on weekends. In financial centers around the world, business hours overlap; as some centers close, others open and begin to trade. The foreign exchange market follows the sun around the earth.

The international date line is located in the western Pacific, and each business day arrives first in the Asia-Pacific financial centers—first Wellington, New Zealand, then Sydney, Australia, followed by Tokyo, Hong Kong, and Singapore. A few hours later, while markets remain active in those Asian centers, trading begins in Bahrain and elsewhere in the Middle East. Later still, when it is late in the business day in Tokyo, markets in Europe open for business. Subsequently, when it is early afternoon in Europe, trading in New York and other U.S. centers starts. Finally, completing the circle, when it is mid- or late-afternoon in the United States, the next day has arrived in the Asia-Pacific area, the first markets there have opened, and the process begins again.

The twenty-four hour market means that exchange rates and market conditions can change at any time in response to developments that can take place at any time. It also means that traders and other market participants must be alert to the possibility that a sharp move in an exchange rate can occur during an off hour, elsewhere in the world. The large dealing institutions have adapted to these conditions, and have introduced various arrangements for monitoring markets and trading on a twenty-four hour basis. Some keep their New York or other trading desks open.
However, foreign exchange activity does not flow evenly. Over the course of a day, there is a cycle characterized by periods of very heavy activity and other periods of relatively light activity. Most of the trading takes place when the largest number of potential counterparties is available or accessible on a global basis. (Figure 3-2 gives a general sense of participation levels in the global foreign exchange market by tracking electronic conversations per hour.) Market liquidity is of great importance to participants. Sellers want to sell when they have access to the maximum number of potential buyers, and buyers want to buy when they have access to the maximum number of potential sellers.

Business is heavy when both the U.S. markets and the major European markets are open—that is, when it is morning in New York and afternoon in London. In the New York market, nearly two-thirds of the day’s activity typically takes place in the morning hours. Activity normally becomes very slow in New York in the mid- to late afternoon, after European markets have closed and before the Tokyo, Hong Kong, and Singapore markets have opened.

Given this uneven flow of business around the clock, market participants often will respond less aggressively to an exchange rate development that occurs at a relatively inactive time of day, and will wait to see whether the development is confirmed when the major markets open. Some institutions pay little attention to developments in less active markets. Nonetheless, the twenty-four hour market does provide a continuous “real-time” market assessment of the ebb and flow of influences and attitudes with respect to the traded currencies, and an opportunity for a quick judgment of unexpected events. With many traders carrying pocket monitors, it has become relatively easy to stay in touch with market...
The market consists of a limited number of major dealer institutions that are particularly active in foreign exchange, trading with customers and (more often) with each other. Most, but not all, are commercial banks and investment banks. These dealer institutions are geographically dispersed, located in numerous financial centers around the world. Wherever located, these institutions are linked to, and in close communication with, each other through telephone, computers, and other electronic means.

There are around 2,000 dealer institutions whose foreign exchange activities are covered by the Bank for International Settlements’ central bank survey, and who, essentially, make up the global foreign exchange market. A much smaller sub-set of those institutions account for the bulk of trading and market-making activity. It is estimated that there are 100-200 market-making banks worldwide; major players are fewer than that.

At a time when there is much talk about an integrated world economy and “the global village,” the foreign exchange market comes closest to functioning in a truly global fashion, linking the various foreign exchange trading centers from around the world into a single, unified, cohesive, worldwide market. Foreign exchange trading takes place among dealers and other market professionals in a large number of individual financial centers—New York, Chicago, Los Angeles, London, Tokyo, Singapore, Frankfurt, Paris, Zurich, Milan, and many, many others. But no matter in which financial center a trade occurs, the same currencies, or rather, bank deposits denominated in the same currencies, are being bought and sold.

A foreign exchange dealer buying dollars in one of those markets actually is buying a dollar-denominated deposit in a bank located in the United States, or a claim of a bank abroad on a dollar deposit in a bank located in the United States. This holds true regardless of the location of the financial center at which the dollar deposit is purchased. Similarly, a dealer buying Deutsche marks, no matter where the purchase is made, actually is buying a mark deposit in a bank in Germany or a claim on a mark deposit in a bank in Germany. And so on for other currencies.

Each nation’s market has its own infrastructure. For foreign exchange market operations as well as for other matters, each country enforces its own laws, banking regulations, accounting rules, and tax code, and, as noted above, it operates its own payment and settlement systems. Thus, even in a global foreign exchange market with currencies traded on essentially the same terms simultaneously in many financial centers, there are different national financial systems and infrastructures through which transactions are executed, and within which currencies are held.

With access to all of the foreign exchange markets generally open to participants from all countries, and with vast amounts of market developments at all times—indeed, too easy, some harassed traders might say. The foreign exchange market provides a kind of never-ending beauty contest or horse race, where market participants can continuously adjust their bets to reflect their changing views.
The dollar is by far the most widely traded currency. According to the 1998 survey, the dollar was one of the two currencies involved in an estimated 87 percent of global foreign exchange transactions, equal to about $1.3 trillion a day. In part, the widespread use of the dollar reflects its substantial international role as: “investment” currency in many capital markets, “reserve” currency held by many central banks, “transaction” currency in many international commodity markets, “invoice” currency in many contracts, and “intervention” currency employed by monetary authorities in market operations to influence their own exchange rates.

Accordingly, a bank in the United States is likely to trade foreign exchange at least as frequently with banks in London, Frankfurt, and other open foreign centers as with other banks in the United States. Surveys indicate that when major dealing institutions in the United States trade with other dealers, 58 percent of the transactions are with dealers located outside the United States. The United States is not unique in that respect. Dealer institutions in other major countries also report that more than half of their trades are with dealers that are across borders; dealers also use brokers located both domestically and abroad.

4. The Market’s Most Widely Traded Currency Is the Dollar

The dollar is by far the most widely traded currency. According to the 1998 survey, the dollar was one of the two currencies involved in an estimated 87 percent of global foreign exchange transactions, equal to about $1.3 trillion a day. In part, the widespread use of the dollar reflects its substantial international role as: “investment” currency in many capital markets, “reserve” currency held by many central banks, “transaction” currency in many international commodity markets, “invoice” currency in many contracts, and “intervention” currency employed by monetary authorities in market operations to influence their own exchange rates.

In addition, the widespread trading of the dollar reflects its use as a “vehicle” currency in foreign exchange transactions, a use that reinforces, and is reinforced by, its international role in trade and finance. For most pairs of currencies, the market practice is to trade each of the two currencies against a common third currency as a vehicle, rather than to trade the two currencies directly against each other. The vehicle currency used most often is the dollar, although by the mid-1990s the Deutsche mark also had become an important vehicle, with its use, especially in Europe, having increased sharply during the 1980s and ’90s.

Thus, a trader wanting to shift funds from one currency to another, say, from Swedish krona to Philippine pesos, will probably sell krona for U.S. dollars and then sell the U.S. dollars for pesos. Although this approach results in two transactions rather than one, it may be the preferred way, since the dollar/Swedish krona market, and the dollar/Philippine peso market are much more active and liquid and have much better information than a bilateral market for the two currencies directly against each other. By using the dollar or some other currency as a vehicle, banks and other foreign exchange market participants can limit more of their working balances to the vehicle currency, rather than holding and managing many currencies, and can concentrate their research and information sources on the vehicle.
Use of a vehicle currency greatly reduces the number of exchange rates that must be dealt with in a multilateral system. In a system of 10 currencies, if one currency is selected as vehicle currency and used for all transactions, there would be a total of nine currency pairs or exchange rates to be dealt with (i.e., one exchange rate for the vehicle currency against each of the others), whereas if no vehicle currency were used, there would be 45 exchange rates to be dealt with. In a system of 100 currencies with no vehicle currencies, potentially there would be 4,950 currency pairs or exchange rates [the formula is: \( n(n-1)/2 \)]. Thus, using a vehicle currency can yield the advantages of fewer, larger, and more liquid markets with fewer currency balances, reduced informational needs, and simpler operations.

The U.S. dollar took on a major vehicle currency role with the introduction of the Bretton Woods par value system, in which most nations met their IMF exchange rate obligations by buying and selling U.S. dollars to maintain a par value relationship for their own currency against the U.S. dollar. The dollar was a convenient vehicle, not only because of its central role in the exchange rate system and its widespread use as a reserve currency, but also because of the presence of large and liquid dollar money and other financial markets, and, in time, the Euro-dollar markets where dollars needed for (or resulting from) foreign exchange transactions could conveniently be borrowed (or placed).

Changing conditions in the 1980s and 1990s altered this situation. In particular, the Deutsche mark began to play a much more significant role as a vehicle currency and, more importantly, in direct “cross trading.”

As the European Community moved toward economic integration and monetary unification, the relationship of the European Monetary System (EMS) currencies to each other became of greater concern than the relationship of their currencies to the dollar. An intra-European currency market developed, centering on the mark and on Germany as the strongest currency and largest economy. Direct intervention in members’ currencies, rather than through the dollar, became widely practiced. Events such as the EMS currency crisis of September 1992, when a number of European currencies came under severe market pressure against the mark, confirmed the extent to which direct use of the DEM for intervening in the exchange market could be more effective than going through the dollar.

Against this background, there was very rapid growth in direct cross rate trading involving the Deutsche mark, much of it against European currencies, during the 1980s and ’90s. (A “cross rate” is an exchange rate between two non-dollar currencies—e.g., DEM/Swiss franc, DEM/pound, and DEM/yen.) As discussed in Chapter 5, there are derived cross rates calculated from the dollar rates of each of the two currencies, and there are direct cross rates that come from direct trading between the two currencies—which can result in narrower spreads where there is a viable market. In a number of European countries, the volume of trading of the local currency against the Deutsche mark grew to exceed local currency trading against the dollar, and the practice developed of using cross rates between the DEM and other European currencies to determine the dollar rates for those currencies.

With its increased use as a vehicle currency and its role in cross trading, the Deutsche mark was involved in 30 percent of global currency turnover in the 1998 survey. That was still far below the dollar (which was involved in 87 percent of global turnover), but well above the Japanese yen (ranked third, at 21 percent), and the pound sterling (ranked fourth, at 11 percent).
5. It is an "Over-the-Counter" Market With an "Exchange-Traded" Segment

Until the 1970s, all foreign exchange trading in the United States (and elsewhere) was handled "over-the-counter," (OTC) by banks in different locations making deals via telephone and telex. In the United States, the OTC market was then, and is now, largely unregulated as a market. Buying and selling foreign currencies is considered the exercise of an express banking power. Thus, a commercial bank in the United States does not need any special authorization to trade or deal in foreign exchange. Similarly, securities firms and brokerage firms do not need permission from the Securities and Exchange Commission (SEC) or any other body to engage in foreign exchange activity. Transactions can be carried out on whatever terms and with whatever provisions are permitted by law and acceptable to the two counterparties, subject to the standard commercial law governing business transactions in the United States.

Although the OTC market is not regulated as a market in the way that the organized exchanges are regulated, regulatory authorities examine the foreign exchange market activities of banks and certain other institutions participating in the OTC market. As with other business activities in which these institutions are engaged, examiners look at trading systems, activities, and exposure, focusing on the safety and soundness of the institution and its activities. Examinations deal with such matters as capital adequacy, control systems, disclosure, sound banking practice, legal compliance, and other factors relating to the safety and soundness of the institution.

The OTC market accounts for well over 90 percent of total U.S. foreign exchange market activity, covering both the traditional (pre-1970) products (spot, outright forwards, and FX swaps) as well as the more recently introduced (post-1970) OTC products (currency options and currency swaps). On the "organized exchanges," foreign exchange products traded are currency futures and certain currency options.

Trading practices on the organized exchanges, and the regulatory arrangements covering the exchanges, are markedly different from those in the OTC market. In the exchanges, trading takes place publicly in a centralized location. Hours, trading practices, and other matters are regulated by the particular exchange; products are standardized. There are margin payments, daily marking to market, and cash settlements through a central clearinghouse. With respect to regulation, exchanges at which currency futures are traded are under the jurisdiction of the Commodity Futures Trading Corporation (CFTC); in the case of currency options, either the CFTC or the Securities and Exchange Commission serves
as regulator, depending on whether securities are traded on the exchange.

Steps are being taken internationally to help improve the risk management practices of dealers in the foreign exchange market, and to encourage greater transparency and disclosure. With respect to the internationally active banks, there has been a move under the auspices of the Basle Committee on Banking Supervision of the BIS to introduce greater consistency internationally to risk-based capital adequacy requirements. Over the past decade, the regulators of a number of nations have accepted common rules proposed by the Basle Committee with respect to capital adequacy requirements for credit risk, covering exposures of internationally active banks in all activities, including foreign exchange. Further proposals of the Basle Committee for risk-based capital requirements for market risk have been adopted more recently. With respect to investment firms and other financial institutions, international discussions have not yet produced agreements on common capital adequacy standards.
The main participants in the market

**ALL ABOUT...**

Most commercial banks in the United States customarily have bought and sold foreign exchange for their customers as one of their standard financial services. But beginning at a very early stage in the development of the over-the-counter market, a small number of large commercial banks operating in New York and other U.S. money centers took on foreign exchange trading as a major business activity. They operated for corporate and other customers, serving as intermediaries and market makers. In this capacity, they transacted business as correspondents for many other commercial banks throughout the country, while also buying and selling foreign exchange for their own accounts. These major dealer banks found it useful to trade with each other frequently, as they sought to find buyers and sellers and to manage their positions. This group developed into an *interbank* market for foreign exchange.

While these commercial banks continue to play a dominant role, being a major dealer in the foreign exchange market has ceased to be their exclusive domain. During the past 25 years, some investment banking firms and other financial institutions have become emulators and direct competitors of the commercial banks as dealers in the over-the-counter market. They now also serve as major dealers, executing transactions that previously would have been handled only by the large commercial banks, and providing foreign exchange services to a variety of customers in competition with the dealer banks. They are now part of the network of foreign exchange dealers that constitutes the U.S. segment of the foreign exchange market. Although it is still called the “interbank” market in foreign exchange, it is more accurately an “interdealer” market.

The 1998 foreign exchange market turnover survey by the Federal Reserve Bank of New York covered the operations of the 93 major foreign exchange dealers in the United States. The total volume of transactions of the reporting dealers, corrected for double-counting among themselves, at $351 billion per day in traditional products, plus $32 billion in currency options and currency swaps, represents the estimated total turnover in the U.S. over-the-counter market in 1998.

To be included in the reporting dealers group surveyed by the Federal Reserve, an institution must be located in the United States and play an active role as a dealer in the market. There are no formal requirements for inclusion, other than having a high enough level of foreign exchange trading activity. Of course, an institution must have a name that is known and accepted to enable it to obtain from other participants the credit lines essential to active participation.

Of the 93 reporting dealers in 1998, 82 were commercial banks, and 11 were investment banks or insurance firms. All of the large U.S. money center banks are active dealers. Most of the 93 institutions are located in New York, but a number of them are based in Boston, Chicago, San Francisco, and other U.S. financial centers. Many of the dealer institutions have outlets in other countries as well as in the United States.

Included in the group are a substantial number of U.S. branches and subsidiaries of major foreign banks—banks from Japan, the United Kingdom, Germany, France, Switzerland, and elsewhere. Many of these branches and agencies specialize in dealing in the home currency of their parent bank. A substantial share of the foreign exchange activity of the
dealers in the United States is done by these U.S. branches and subsidiaries of foreign banks.

Some, but not all, of the 93 reporting dealers in the United States act as market makers for one or a number of currencies. A market maker is a dealer who regularly quotes both bids and offers for one or more particular currencies and stands ready to make a two-sided market for its customers. Thus, during normal hours a market maker will, in principle, be willing to commit the firm's capital, within limits, to complete both buying and selling transactions at the prices he quotes, and to seek to make a profit on the spread, or difference, between the two prices. In order to make a profit from this activity, the market maker must manage the firm's own inventory and position very carefully, and accurately perceive the short-term trends and prospects of the market. A market maker is more or less continuously in the market, trading with customers and balancing the flow of these activities with offsetting trades on the firm's own account. In foreign exchange, as in other markets, market makers are regarded as helpful to the functioning of the market—contributing to liquidity and short-run price stability, providing useful price information, smoothing imbalances in the flow of business, maintaining the continuity of trading, and making it easier to trade promptly.

According to the 1998 survey, as shown in Figure 4-1, 49 percent of the foreign exchange trading activity in the over-the-counter market represented “interdealer” transactions, that is, trading by the 93 reporting dealers among themselves and with comparable dealers abroad. Of the remaining 51 percent of total foreign exchange transactions, financial (non-dealer) customers accounted for 31 percent, and non-financial customers 20 percent.

The range of financial and nonfinancial customers includes such counterparties as: smaller commercial banks and investment banks that do not act as major dealers, firms and corporations that are buying or selling foreign exchange because they (or the customers for whom they are acting) are in the process of buying or selling something else (a product, a service, or a financial asset), managers of money funds, mutual funds, hedge
funds, and pension funds; and even high net worth individuals. For such intermediaries and end-users, the foreign exchange transaction is part of the payments process—that is, a means of completing some commercial, investment, speculative, or hedging activity.

Over the years, the universe of foreign exchange end-users has changed markedly, reflecting the changing financial environment. By far the most striking change has been the spectacular growth in the activity of those engaged in international capital movements for investment purposes. A generation ago, with relatively modest overseas investment flows, foreign exchange activity in the United States was focused on international trade in goods and services. Importers and exporters accounted for the bulk of the foreign exchange that was bought from and sold to final customers in the United States as they financed the nation’s overseas trade.

But investment to and from overseas—as indicated by the capital flows, cross-border bank claims, and securities transactions reported in Chapter 1—has expanded far more rapidly than has trade. Institutional investors, insurance companies, pension funds, mutual funds, hedge funds, and other investment funds have, in recent years, become major participants in the foreign exchange markets. Many of these investors have begun to take a more global approach to portfolio management. Even though these institutions in the aggregate still hold only a relatively small proportion (5 to 10 percent) of their investments in foreign currency denominated assets, the amounts these institutions control are so large that they have become key players in the foreign exchange market. In the United States, for example, mutual funds have grown to more than $5 trillion in total assets, pension funds are close to $3 trillion, and insurance companies about $2 1/2 trillion. The hedge funds, though far smaller in total assets, also are able to play an important role, given their frequent use of high leverage and, in many cases, their investors' financial strength and higher tolerance for risk.

Given the large magnitudes of these institutions’ assets, even a modest shift in emphasis toward foreign investment can mean large increases in foreign exchange transactions. In addition, there has been a tendency among many funds managers worldwide to manage their investments much more actively, and with greater focus on short-term results. Rapid growth in derivatives and the development of new financial instruments also have fostered international investment.

Reflecting these developments, portfolio investment has come to play a very prominent role in the foreign exchange market and accounts for a large share of foreign exchange market activity. The role of portfolio investment may continue to grow rapidly, as fund managers and investors increase the level of funds invested abroad, which is still quite modest, especially relative to the corresponding levels in many other advanced economies.

3. CENTRAL BANKS

All central banks participate in their nations’ foreign exchange markets to some degree, and their operations can be of great importance to those markets. But central banks differ, not only in the extent of their participation, but also in the manner and purposes of their involvement. The
role of the Federal Reserve in the foreign exchange market is discussed more fully in Chapter 9.

Intervention operations designed to influence foreign exchange market conditions or the exchange rate represent a critically important aspect of central banks’ foreign exchange transactions. However, the intervention practices of individual central banks differ greatly with respect to objectives, approaches, amounts, and tactics.

Unlike the days of the Bretton Woods par value system (before 1971), nations are now free, within broad rules of the IMF, to choose the exchange rate regime they feel best suits their needs. The United States and many other developed and developing nations have chosen an “independently floating” regime, providing for a considerable degree of flexibility in their exchange rates. But a large number of countries continue to peg their currencies, either to the U.S. dollar or some other currency, or to a currency basket or a currency composite, or have chosen some other regime to limit or manage flexibility of the home currency (Figure 4-2). The choice of exchange rate regime determines the basic framework within which each central bank carries out its intervention activities.

The techniques employed by a central bank to maintain an exchange rate that is pegged or closely tied to another currency are straightforward and have limited room for maneuver or change. But for the United States and others with more flexible regimes, the approach to intervention can be

*The International Monetary Fund classification of exchange rate regimes with “independently floating” representing the highest degree of flexibility, followed by “managed floating”; of the seven largest industrial democracies, four (United States, Japan, Canada, and United Kingdom) belong to the independently floating group, and three (France, Germany, and Italy) participate in the European Monetary System arrangement.

1Refers to the arrangement under the European Monetary System covering Austria, Belgium, Denmark, Finland, France, Germany, Ireland, Italy, Luxembourg, Netherlands, Portugal, and Spain.

2Refers to countries where exchange rates are pegged to various “baskets” of currencies, including two countries (Libya and Myanmar) that peg their currencies to the SDR basket.
the main participants in the market

ALL ABOUT...

varied in many ways—whether and when to intervene, in which currencies and geographic markets, in what amounts, aggressively or less so, openly or discreetly, and in concert with other central banks or not. The resolution of these and other issues depends on an assessment of market conditions and the objectives of the intervention. As discussed in Chapter 9, the United States, operating under the same broad policy guideline over a number of years, has experienced both periods of relatively heavy intervention and periods of minimal activity.

Foreign exchange market intervention is not the only reason central banks buy and sell foreign currencies. Many central banks serve as their government’s principal international banker, and handle most, and in some cases all, foreign exchange transactions for the government as well as for other public sector enterprises, such as the post office, electric power utilities, and nationalized airline or railroad. Consequently, even without its own intervention operations, a central bank may be operating in the foreign exchange market in order to acquire or dispose of foreign currencies for some government procurement or investment purpose. A central bank also may seek to accumulate, reallocate among currencies, or reduce its foreign exchange reserve balances. It may be in the market as agent for another central bank, using that other central bank’s resources to assist it in influencing that nation’s exchange rate. Alternatively, it might be assisting another central bank in acquiring foreign currencies needed for the other central bank’s activities or business expenditures.

Thus, for example, the Foreign Exchange Desk of the Federal Reserve Bank of New York engages in intervention operations only occasionally. But it usually is in the market every day, buying and selling foreign currencies, often in modest amounts, for its “customers” (i.e., other central banks, some U.S. agencies, and international institutions). This “customer” business provides a useful service to other central banks or agencies, while also enabling the Desk to stay in close touch with the market for the currencies being traded.

In the Over-the-Counter Market

The role of a broker in the OTC market is to bring together a buyer and a seller in return for a fee or commission. Whereas a “dealer” acts as principal in a transaction and may take one side of a trade for his firm’s account, thus committing the firm’s capital, a “broker” is an intermediary who acts as agent for one or both parties in the transaction and, in principle, does not commit capital. The dealer hopes to find the other side to the transaction and earn a spread by closing out the position in a subsequent trade with another party, while the broker relies on the commission received for the service provided (i.e., bringing the buyer and seller together). Brokers do not take positions or face the risk of holding an inventory of currency balances subject to exchange rate fluctuations. In over-the-counter trading, the activity of brokers is confined to the dealers market. Brokers, including “voice” brokers located in the United States and abroad, as well as electronic brokerage systems, handle about one-quarter of all U.S. foreign exchange transactions in the OTC market. The remaining three-quarters takes the form of “direct dealing” between dealers and other institutions in the market. The present
24 percent share of brokers is down from about 50 percent in 1980 (Figure 4-3). The number of foreign exchange brokers in the United States was 9 in 1998, including voice brokers and the two major automated order-matching, or electronic brokerage systems. The number of brokers surveyed is down from 17 in 1995.

The share of business going through brokers varies in different national markets, because of differences in market structure and tradition. Earlier surveys showed brokers’ share averages as low as 10-15 percent in some markets (Switzerland and South Africa) and as high as 45-50 percent in others (France, Netherlands, and Ireland). Many U.S. voice broker firms have branches or affiliations with brokers in other countries. It is common for a deal to be brokered between a bank in the United States and one in London or elsewhere during the period of the day when both markets are active.

In the OTC market, the extent to which brokering, rather than direct dealing, is used varies, depending on market conditions, the currency and type of transaction being undertaken, and a host of other factors. Size is one factor—the average transaction is larger in the voice brokers market than in the market as a whole. Using a broker can save time and effort, providing quick access to information and a large number of institutions’ quotes, though at the cost of a fee. Operating through a broker can provide at least a degree of confidentiality, when a trader wants to pursue a particular strategy without his name being seen very widely around the market in general (counterparties to each transaction arranged by a broker will, of course, be informed, but after the fact). The brokers market provides access to a wide selection of banks, which means greater liquidity. In addition, a market maker may wish to show only one side of the price—that is, indicate a price at which the market maker is willing to buy, or a price at which the market maker is willing to sell, but not both—which can be done in the brokers market, but generally not in direct dealing. Of course, a trader will prefer to avoid paying a broker’s fee if possible, but doesn’t want to miss a deal just to avoid a fee.

Foreign exchange brokerage is a highly competitive field and the brokers must provide service of high quality in order to make a profit. Although some tend to specialize in particular currencies, they are all rivals for the same business in the inter-dealer market. Not only do brokers compete among themselves for broker business—voice brokers against each other, against voice brokers located abroad, and against electronic broking systems—but the broker community as a whole competes against banks and other dealer institutions that have the option of dealing directly with each other, both in their local markets and abroad, and avoiding the brokers and the brokers’ fees.
Voice Brokers
Skill in carrying out operations for customers and the degree of customers’ confidence determine a voice broker’s success. To perform their function, brokers must stay in close touch with a large number of dealers and know the rates at which market participants are prepared to buy and sell. With 93 active dealers in New York and a much larger number in London, that can be a formidable task, particularly at times of intense activity and volatile rate movements. Information is the essential ingredient of the foreign exchange market and the player with the latest, most complete, and most reliable information holds the best cards. As one channel, many voice brokers have open telephone lines to many trading desks, so that a bank trader dealing in, say, sterling, can hear over squawk boxes continuous oral reports of the activity of brokers in that currency, the condition of the market, the number of transactions occurring, and the rates at which trading is taking place, though traders do not hear the names of the two banks in the transaction or the specific amounts of the trade.

Automated Order-Matching, or Electronic Broking Systems
Until 1992, all brokered business in the U.S. OTC market was handled by voice brokers. But during the past few years, electronic broker systems (or automated order-matching systems) have gained a significant share of the market for spot transactions. The two electronic broking systems currently operating in the United States are Electronic Brokerage Systems, or EBS, and Reuters 2000-2. In the 1998 survey, electronic broking accounted for 13 percent of total market volume in the United States, more than double its market share three years earlier. In the brokers market, 57 percent of turnover is now conducted through order-matching systems, compared with 18 percent in 1995.

With these electronic systems, traders can see on their screens the bid and offer rates that are being quoted by potential counterparties acceptable to that trader’s institution (as well as quotes available in the market more broadly), match an order, and make the deal electronically, with back offices receiving proper notification.

The electronic broking systems are regarded as fast and reliable. Like a voice broker, they offer a degree of anonymity. The counterparty is not known until the deal is struck, and then only to the other counterparty. Also, the systems can automatically manage credit lines. A trader puts in a credit limit for each counterparty that he is willing to deal with, and when the limit is reached, the system automatically disallows further trades. The fees charged for this computerized service are regarded as competitive. The automated systems are already widely used for certain standardized operations in the spot market, particularly for smaller-sized transactions in the most widely traded currency pairs. Many market observers expect these electronic broking or order-matching systems to expand their activities much further and to develop systems to cover additional products, to the competitive disadvantage, in particular, of the voice brokers. Some observers believe that automated systems and other technological advances have substantially slowed the growth in market turnover by reducing “daisy chaining” and the “recycling” of transactions through the markets, as well as by other means. (Electronic broking is discussed further in Chapter 7.)
In the Exchange-Traded Market
In the exchange-traded segment of the market, which covers currency futures and exchange-traded currency options, the institutional structure and the role of brokers are different from those in the OTC market.

In the exchanges, orders from customers are transmitted to a floor broker. The floor broker then tries to execute the order on the floor of the exchange (by open outcry), either with another floor broker or with one of the floor traders, also called “locals,” who are members of the exchange on the trading floor, executing trades for themselves.

Each completed deal is channeled through the clearinghouse of that particular exchange by a clearing member firm. A participant that is not a clearing member firm must have its trades cleared by a clearing member.

The clearinghouse guarantees the performance of both parties, assuring that the long side of every short position will be met, and that the short side of every long position will be met. This requires (unlike in the OTC market) payment of initial and maintenance margins to the clearinghouse (by buyers and sellers of futures and by writers, but not holders, of options). In addition, there is daily marking to market and settlement. Thus, frequent payments to (and receipts from) brokers and clearing members may be called for by customers to meet these daily settlements.
**CHAPTER 5**

Chapter 3 noted that the United States has both an *over-the-counter* market in foreign exchange and an *exchange-traded* segment of the market. The OTC market is the U.S. portion of an international OTC network of major dealers—mainly but not exclusively banks—operating in financial centers around the world, trading with each other and with customers, via computers, telephones, and other means. The *exchange-traded* market covers trade in a limited number of foreign exchange products on the floors of organized exchanges located in Chicago, Philadelphia, and New York.

This chapter describes the foreign exchange products traded in the OTC market. It covers the three "traditional" foreign exchange instruments—*spot*, *outright forwards*, and *FX swaps*, which were the *only* instruments traded before the 1970s, and which still constitute the overwhelming share of all foreign exchange market activity. It also covers two more recent products in which OTC trading has developed since the 1970s—*currency swaps* and *OTC currency options*.

The next chapter describes *currency futures* and *exchange-traded currency options*, which currently are traded in U.S. exchanges.

## 1. SPOT

A *spot* transaction is a straightforward (or “outright”) exchange of one currency for another. The spot rate is the current market price, the benchmark price.

Spot transactions do not require *immediate* settlement, or payment “on the spot.” By convention, the settlement date, or “value date,” is the *second* business day after the “deal date” (or “trade date”) on which the transaction is agreed to by the two traders. The two-day period provides ample time for the two parties to confirm the agreement and arrange the clearing and necessary debiting and crediting of bank accounts in various international locations.

Exceptionally, spot transactions between the Canadian dollar and U.S. dollar conventionally are settled *one* business day after the deal, rather than *two* business days later, since Canada is in the same time zone as the United States and an earlier value date is feasible.

It is possible to trade for value dates *in advance* of the spot value date two days hence (“pre-spot” or “ante-spot”). Traders can trade for “value tomorrow,” with settlement one business day after the deal date (one day before spot); or even for “cash,” with settlement on the deal date (two days before spot). Such transactions are a very small part of the market, particularly same day “cash” transactions for the U.S. dollar against European
or Asian currencies, given the time zone differences. Exchange rates for cash or value tomorrow transactions are based on spot rates, but differ from spot, reflecting in part, the fact that interest rate differences between the two currencies affect the cost of earlier payment. Also, pre-spot trades are much less numerous and the market is less liquid.

A spot transaction represents a direct exchange of one currency for another, and when executed, leads to transfers through the payment systems of the two countries whose currencies are involved. In a typical spot transaction, Bank A in New York will agree on June 1 to sell $10 million for Deutsche marks to Bank B in Frankfurt at the rate of, say, DEM 1.7320 per dollar, for value June 3. On June 3, Bank B will pay DEM 17.320 million for credit to Bank A’s account at a bank in Germany, and Bank A will pay $10 million for credit to Bank B’s account at a bank in the United States. The execution of the two payments completes the transaction.

There is a Buying Price and a Selling Price
In the foreign exchange market there are always two prices for every currency—one price at which sellers of that currency want to sell, and another price at which buyers want to buy. A market maker is expected to quote simultaneously for his customers both a price at which he is willing to sell and a price at which he is willing to buy standard amounts of any currency for which he is making a market.

How Spot Rates are Quoted: Direct and Indirect Quotes, European and American Terms
Exchange rate quotes, as the price of one currency in terms of another, come in two forms: a “direct” quotation is the amount of domestic currency (dollars and cents if you are in the United States) per unit of foreign currency and an “indirect” quotation is the amount of foreign currency per unit of domestic currency (per dollar if you are in the United States).

The phrase “American terms” means a direct quote from the point of view of someone located in the United States. For the dollar, that means that the rate is quoted in variable amounts of U.S. dollars and cents per one unit of foreign currency (e.g., $0.5774 per DEM1). The phrase “European terms” means a direct quote from the point of view of someone located in Europe. For the dollar, that means variable amounts of foreign currency per one U.S. dollar (or DEM 1.7320 per $1).

In daily life, most prices are quoted “directly,” so when you go to the store you pay x dollars and y cents for one loaf (unit) of bread. For many years, all dollar exchange rates also were quoted directly. That meant dollar exchange rates were quoted in European terms in Europe, and in American terms in the United States. However, in 1978, as the foreign exchange market was integrating into a single global market, for convenience, the practice in the U.S. market was changed—at the initiative of the brokers community—to conform to the European convention. Thus, OTC markets in all countries now quote dollars in European terms against nearly all other currencies (amounts of foreign currency per $1). That means that the dollar is nearly always the base currency, one unit of which (one dollar) is being bought or sold for a variable amount of a foreign currency.

There are still exceptions to this general rule, however. In particular, in all OTC markets around the world, the pound sterling continues to be quoted as the base currency against the dollar and other currencies. Thus, market makers and brokers everywhere quote the pound sterling at x dollars and cents per pound, or y DEM per pound, and so forth. The
United Kingdom did not adopt a decimal currency system until 1971, and it was much easier mathematically to quote and trade in terms of variable amounts of foreign currency per pound than the other way around.

Certain currencies historically linked to the British pound—the Irish, Australian, and New Zealand currencies—are quoted in the OTC market in the same way as the pound: variable amounts of dollars and cents per unit. The SDR and the ECU, composite currency units of the IMF and the European Monetary Union, also are quoted in dollars and cents per SDR or ECU. Similarly, it is expected that the euro will be quoted in dollars and cents per euro, at least among dealers. But all other currencies traded in the OTC market are quoted in variable amounts of foreign currency per one dollar.

Direct and indirect quotes are reciprocals, and either can easily be determined from the other. In the United States, the financial press typically reports the quotes both ways, as shown in the excerpt from The New York Times in Figure 5-2 at the end of the chapter.

The third and fourth columns show the quotes for the previous two days in “European terms”—the foreign currency price of one dollar—which is the convention used for most exchange rates by dealers in the OTC market.

The first and second columns show the (reciprocal) quotes for the same two days in American terms—the price in dollars and cents of one unit of each of various foreign currencies—which is the approach sometimes used by traders in dealings with commercial customers, and is also the convention used for quoting dollar exchange rates in the exchange-traded segment of the U.S. foreign exchange market.

There Is a Base Currency and a Terms Currency
Every foreign exchange transaction involves two currencies—and it is important to keep straight which is the base currency (or quoted, underlying, or fixed currency) and which is the terms currency (or counter currency). A trader always buys or sells a fixed amount of the “base” currency—as noted above, most often the dollar—and adjusts the amount of the “terms” currency as the exchange rate changes.

The terms currency is thus the numerator and the base currency is the denominator. When the numerator increases, the base currency is strengthening and becoming more expensive; when the numerator decreases, the base currency is weakening and becoming cheaper.

In oral communications, the base currency is always stated first. For example, a quotation for “dollar-yen” means the dollar is the base and the denominator, and the yen is the terms currency and the numerator; “dollar-swissie” means that the Swiss franc is the terms currency; and “sterling-dollar” (usually called “cable”) means that the dollar is the terms currency. Currency codes are also used to denote currency pairs, with the base currency usually presented first, followed by an oblique. Thus “dollar-yen” is USD/JPY; “dollar-swissie” is USD/CHF; and “sterling-dollar” is GBP/USD.

Bids and Offers Are for the Base Currency
Traders always think in terms of how much it costs to buy or sell the base currency. A market maker’s quotes are always presented from the market maker’s point of view, so the bid price is the amount of terms currency that the market maker will pay for a unit of the base currency; the offer price is the amount of terms currency the market maker will charge for a unit of the base currency. A market maker asked for a quote on “dollar-swissie” might respond “1.4975-85,” indicating a bid price of CHF...
1.4975 per dollar and an offer price of CHF 1.4985 per dollar. Usually the market maker will simply give the quote as “75-85,” and assume that the counterparty knows that the “big figure” is 1.49. The bid price always is offered first (the number on the left), and is lower (a smaller amount of terms currency) than the offer price (the larger number on the right). This differential is the dealer’s spread.

**Quotes Are in Basis Points**

For most currencies, bid and offer quotes are presented to the fourth decimal place—that is, to one-hundredth of one percent, or 1/10,000th of the terms currency unit, usually called a “pip.” However, for a few currency units that are relatively small in absolute value, such as the Japanese yen and the Italian lira, quotes may be carried to two decimal places and a “pip” is 1/100 of the terms currency unit. In any market, a “pip” or a “tick” is the smallest amount by which a price can move in that market, and in the foreign exchange market “pip” is the term commonly used.

**Cross Rate Trading**

Cross rates, as noted in Chapter 3, are exchange rates in which the dollar is neither the base nor the terms currency, such as “mark-yen,” in which the DEM is the base currency; and “sterling-mark,” in which the pound sterling is the base currency. In cross trades, either currency can be made the base, although there are standard pairs—mark-yen, sterling-swissie, etc. As usual, the base currency is mentioned first.

There are both derived cross rates and directly traded cross rates. Historically, cross rates were derived from the dollar rates of the two named currencies, even if the transaction was not actually channeled through the dollar. Thus, a cross rate for sterling-yen would be derived from the sterling-dollar and dollar-yen rates. That continues to be the practice for many currency pairs, as described in Box 5.1, but for other pairs, viable markets have developed and direct trading sets the cross rates, within the boundary rates established by the derived cross rate calculations.

---

**Deriving Cross Rates From Dollar Exchange Rates**

There are simplified, short-cut ways to derive cross rates from the dollar exchange rates of the two cross currencies, by cross dividing or by multiplying.

There are three cases—the case in which the dollar exchange rates of both of the cross rate currencies are quoted “indirectly”; the case in which both currencies are quoted “directly”; and the case in which one is quoted indirectly and the other is quoted directly.

**Cass 1. If both** of the cross rate currencies are quoted against the dollar in the more common indirect or European terms, for example, “dollar-Swiss franc” and “dollar-yen,” to get a Swiss franc-yen derived cross rate, cross divide as follows:

- for the cross rate bid: divide the bid of the cross rate terms currency by the offer of the base currency;
- for the cross rate offer: divide the offer of the terms currency by the bid of the base currency.

Thus, if the dollar-swissie rate is 1.5000-10 and the dollar-yen rate is 100.00-10, for a Swiss franc-yen derived cross rate: the bid would be 100.00 divided by 1.5010, or 66.6223 yen per Swiss franc, and the offer would be 100.10 divided by 1.5000, or 66.7333 yen per Swiss franc.
During the 1980s and '90s, there was a very large expansion of direct cross trading, in which the dollar was not involved either as metric or as medium of exchange. Much of this direct cross trading activity involved the Deutsche mark. Direct trading activity between the mark and other European currencies developed to the point where most trading of currencies in the European Monetary System took place directly through cross rates, and the most widely direct-traded crosses came to be used to quote rates for other, less widely traded currency pairs. By the mid-1990s, mark-yen, sterling-mark, mark-French franc (or mark-Paris), and mark-Swiss all were very actively traded pairs.

Deutsche mark cross trading with European currencies developed to the point where rates in the New York market for dollar-lira, dollar-French franc, etc., were usually calculated from the mark-lira, mark-French franc, etc., particularly during the afternoon in New York, when European markets were closed.
An outright forward transaction, like a spot transaction, is a straightforward single purchase/sale of one currency for another. The only difference is that spot is settled, or delivered, on a value date no later than two business days after the deal date, while outright forward is settled on any pre-agreed date three or more business days after the deal date. Dealers use the term “outright forward” to make clear that it is a single purchase or sale on a future date, and not part of an “FX swap” (described later).

There is a specific exchange rate for each forward maturity of a currency, almost always different from the spot rate. The exchange rate at which the outright forward transaction is executed is fixed at the outset. No money necessarily changes hands until the transaction actually takes place, although dealers may require some customers to provide collateral in advance.

Outright forwards can be used for a variety of purposes—covering a known future expenditure, hedging, speculating, or any number of commercial, financial, or investment purposes. The instrument is very flexible, and forward transactions can be tailored and customized to meet the particular needs of a customer with respect to currency, amount, and maturity date. Of course, customized forward contracts for non-standard dates or amounts are generally more costly and less liquid, and more difficult to reverse or modify in the event of need than are standard forward contracts. Also, forward contracts for minor currencies and exotic currencies can be more difficult to arrange and more costly.

With the launching of the euro in 1999, major structural changes in cross trading activity can be expected. With the euro replacing a number of European currencies, much of the earlier cross trading will no longer be required. What role the euro itself may play as a vehicle currency remains to be seen.

2. OUTRIGHT FORWARDS

An outright forward transaction, like a spot transaction, is a straightforward single purchase/sale of one currency for another. The only difference is that spot is settled, or delivered, on a value date no later than two business days after the deal date, while outright forward is settled on any pre-agreed date three or more business days after the deal date. Dealers use the term “outright forward” to make clear that it is a single purchase or sale on a future date, and not part of an “FX swap” (described later).

There is a specific exchange rate for each forward maturity of a currency, almost always different from the spot rate. The exchange rate at which the outright forward transaction is executed is fixed at the outset. No money necessarily changes hands until the transaction actually takes place, although dealers may require some customers to provide collateral in advance.

Outright forwards can be used for a variety of purposes—covering a known future expenditure, hedging, speculating, or any number of commercial, financial, or investment purposes. tend toward an equilibrium point at which any difference in Eurocurrency interest rates between the two currencies would be exactly offset, or neutralized, by a premium or discount in the forward rate.

If, for example, six-month Euro-dollar deposits pay interest of 5 percent per annum, and six-month Euro-yen deposits pay interest of 3 percent per annum, and if there is no premium or discount on the forward yen against the forward dollar, there would be an opportunity for “round-tripping” and an arbitrage profit with no exchange risk. Thus, it would pay to borrow yen at 3 percent, sell the yen spot for dollars and simultaneously resell dollars forward for yen six months hence, meanwhile investing the dollars at the higher interest rate of 5 percent for the six-month period. This arbitrage opportunity would tend to drive up the forward exchange rate of the yen relative to the dollar (or force some other adjustment) until there were an equal return on the two investments after taking into account the cost of covering the forward exchange risk.

Similarly, if short-term dollar investments and short-term yen investments both paid the same interest rate, and if there were a premium on the forward yen against the forward dollar, there would once again be an opportunity for an arbitrage profit with no exchange risk, which again would tend to reduce the premium on the forward yen (or force some other adjustment) until there were an equal return on the two investments after covering the cost of the forward exchange risk.

In this state of equilibrium, or condition of covered interest rate parity, an investor (or a borrower) who operates in the forward exchange market will realize the same domestic return (or pay the same domestic cost) whether investing (borrowing) in his domestic currency or in a foreign currency, net of the costs of forward exchange rate cover. The forward exchange rate should offset, or neutralize, the interest rate differential between the two currencies.

The forward rate in the market can deviate from this theoretical, or implied, equilibrium rate derived from the interest rate differential to the extent that there are significant costs, restrictions, or market inefficiencies that prevent arbitrage from taking place in a timely manner. Such constraints could take the form of transaction costs, information gaps, government regulations, taxes, unavailability of comparable investments (in terms of risk, maturity, amount, etc.), and other impediments or imperfections in the capital markets. However, today's large and deregulated foreign exchange markets and Eurocurrency deposit markets for the dollar and other heavily traded currencies are generally free of major impediments.

Role of the Offshore Deposit Markets for Euro-Dollars and Other Currencies

Forward contracts have existed in commodity markets for hundreds of years. In the foreign exchange markets, forward contracts have been traded since the nineteenth century, and the concept of interest arbitrage has been understood and described in economic literature for a long time. (Keynes wrote about it and practiced it in the 1920s.) But it was the development of the offshore Eurocurrency deposit markets—the markets for offshore deposits in dollars and other major currencies—in the 1950s and ‘60s that facilitated and refined the process of interest rate arbitrage in practice and brought it to its present high degree of efficiency, closely linking the foreign exchange market and the money markets of the major nations, and equalizing returns through the two channels.
With large and liquid offshore deposit markets in operation, and with information transfers greatly improved and accelerated, it became much easier and quicker to detect any significant deviations from covered interest rate parity, and to take advantage of any such arbitrage opportunities. From the outset, deposits in these offshore markets were generally free of taxes, reserve requirements, and other government restrictions. The offshore deposit markets in London and elsewhere quickly became very convenient for, and closely attached to, the foreign exchange market. These offshore Eurocurrency markets for the dollar and other major currencies were, from the outset, handled by the banks’ foreign exchange trading desks, and many of the same business practices were adopted. These deposits trade over the telephone like foreign exchange, with a bid/offer spread, and they have similar settlement dates and other trading conventions. Many of the same counterparties participate in both markets, and credit risks are similar. It is thus no surprise that the interest rates in the offshore deposit market in London came to be used for interest parity and arbitrage calculations and operations. Dealers keep a very close eye on the interest rates in the London market when quoting forward rates for the major currencies in the foreign exchange market. For currencies not traded in the offshore Eurocurrency deposit markets in London and elsewhere, deposits in domestic money markets may provide a channel for arbitraging the forward exchange rate and interest rate differentials.

**How Forward Rates are Quoted by Traders**

Although spot rates are quoted in *absolute* terms—say, x yen per dollar—forwards, as a matter of convenience are quoted among dealers in *differentials*—that is, in premiums or discounts from the spot rate. The premium or discount is measured in “points,” which represent the interest rate differential between the two currencies for the period of the forward, converted into foreign exchange. Specifically, points are the amount of foreign exchange (or basis points) that will neutralize the interest rate differential between two currencies for the applicable period. Thus, if interest rates are *higher* for currency A than currency B, the points will be the number of basis points to *subtract* from currency A’s spot exchange rate to yield a forward exchange rate that neutralizes or offsets the interest rate differential (see Box 5-2). Most forward contracts are arranged so that, at the outset, the present value of the contract is zero.

Traders in the market thus know that for any currency pair, if the base currency earns a
and the Swiss franc is the terms currency, with 6 percent interest in the offshore market, and the spot rate is CHF 1.6000 per dollar, then the points for a six-month (181-day) forward rate would be 78. (Most currencies use a 360-day interest rate year, except the pound sterling and a few others, which use a 365-day year.)

\[
\text{Points} = \frac{1.6000 \times \left(\frac{0.06 \times 181}{360}\right)}{1 + \left(\frac{0.05 \times 180}{360}\right)} - 1 = 78
\]

The six month outright forward rate would be CHF 1.6078 per dollar.

- The above generalized formula takes no account of the differences between borrowing and lending rates in the offshore deposit market. In pricing possible forward transactions, a trader would take account of those differences, calculate the costs of putting together the deal, determine the “boundary” rates, and perhaps shade the price to reflect competitive quotes, perspectives on market performance, the trader’s own portfolio of existing contracts, and other factors.

- The higher interest rate than the terms currency, the base currency will trade at a forward discount, or below the spot rate; and if the base currency earns a lower interest rate than the terms currency, the base currency will trade at a forward premium, or above the spot rate. Whichever side of the transaction the trader is on, the trader won’t gain (or lose) from both the interest rate differential and the forward premium/discount. A trader who loses on the interest rate will earn the forward premium, and vice versa.

Traders have long used rules of thumb and shortcuts for calculating whether to add or subtract the points. Points are subtracted from the spot rate when the interest rate of the base currency is the higher one, since the base currency should trade at a forward discount; points are added when the interest rate of the base currency is the lower one, since the base currency should trade at a forward premium. Another rule of thumb is that the points must be added when the small number comes first in the quote of the differential, but subtracted when the larger number comes first. For example, the spot CHF might be quoted at “1.5020–30,” and the 3-month forward at “40–60” (to be added) or “60–40” (to be subtracted). Also, the spread will always grow larger when shifting from the spot quote to the forward quote. Screens now show positive and negative signs in front of points, making the process easier still.

- Non-Deliverable Forwards (NDFs)

In recent years, markets have developed for some currencies in “non-deliverable forwards.” This instrument is in concept similar to an outright forward, except that there is no physical delivery or transfer of the local currency. Rather, the agreement calls for settlement of the net amount in dollars or other major transaction currency. NDFs can thus be arranged offshore without the need for access to the local currency markets, and they broaden hedging opportunities against exchange rate risk in some currencies otherwise considered unhedgeable. Use of NDFs with respect to certain currencies in Asia and elsewhere is growing rapidly.
In the spot and outright forward markets, one currency is traded outright for another, but in the FX swap market, one currency is swapped for another for a period of time, and then swapped back, creating an exchange and re-exchange.

An **FX swap** has two separate legs settling on two different value dates, even though it is arranged as a single transaction and is recorded in the turnover statistics as a single transaction. The two counterparties agree to exchange two currencies at a particular rate on one date (the “near date”) and to reverse payments, almost always at a different rate, on a specified subsequent date (the “far date”). Effectively, it is a spot transaction and an outright forward transaction going in opposite directions, or else two outright forwards with different settlement dates, and going in opposite directions. If both dates are less than one month from the deal date, it is a “short-dated swap”; if one or both dates are one month or more from the deal date, it is a “forward swap.”

The two legs of an FX swap can, in principle, be attached to any pair of value dates. In practice, a limited number of standard maturities account for most transactions. The first leg usually occurs on the spot value date, and for about two-thirds of all FX swaps the second leg occurs within a week. However, there are FX swaps with longer maturities. Among dealers, most of these are arranged for even or straight dates—e.g., one week, one month, three months—but odd or broken dates are also traded for customers.

The FX swap is a standard instrument that has long been traded in the over-the-counter market. Note that it provides for one exchange and one re-exchange only, and not a stream of payments. The FX swap thus differs from the **interest rate swap**, which provides for an exchange of a stream of interest payments in the same currency but with no exchange of principal; it also differs from the **currency swap** (described later), in which counterparties exchange and re-exchange principal and streams of fixed or floating interest payments in two different currencies.

In the **spot and outright forward markets**, a fixed amount of the base currency (most often the dollar) is always traded for a variable amount of the terms currency (most often a non-dollar currency). However, in the **FX swap market**, a trade for a fixed amount of either currency can be arranged.

There are two kinds of FX swaps: a **buy/sell** swap, which means buying the fixed, or base, currency on the near date and selling it on the far date; and a **sell/buy** swap, which means selling the fixed currency on the near date and buying it on the far date. If, for example, a trader bought a fixed amount of pounds sterling spot for dollars (the exchange) and sold those pounds sterling six months forward for dollars (the re-exchange), that would be called a **buy/sell sterling swap**.

**Why FX Swaps Are Used**
The popularity of FX swaps reflects the fact that banks and others in the dealer, or interbank, market often find it useful to shift temporarily into or out of one currency in exchange for a second currency without incurring the exchange rate risk of holding an open position or exposure in the currency that is temporarily held. This avoids a change in currency exposure, and differs from the spot or outright forward, where the purpose is to change a currency exposure. The use of FX swaps is similar to actual borrowing and lending of currencies on a collateralized basis. FX swaps provide a way of using the foreign exchange...
The Foreign Exchange Market in the United States

markets as a funding instrument and an alternative to borrowing and lending in the Euro-dollar and other offshore markets. They are widely used by traders and other market participants for managing liquidity and shifting delivery dates, for hedging, speculation, taking positions on interest rates, and other purposes.

Pricing FX Swaps

The cost of an FX swap is determined by the interest rate differential between the two swapped currencies. Just as in the case of outright forwards, arbitrage and the principle of covered interest rate parity will operate to make the cost of an FX swap equal to the foreign exchange value of the interest rate differential between the two currencies for the period of the swap.

The cost of an FX swap is measured by swap points, or the foreign exchange equivalent of the interest rate differential between two currencies for the period. The difference between the amounts of interest that can be earned on the two currencies during the period of the swap can be calculated by formula (see Box 5-4). The counterparty who holds for the period of the swap the currency that pays the higher interest rate will pay the points, neutralizing the interest rate differential and equalizing the return on the two currencies; and the counterparty who holds the currency that pays the lower interest will earn or receive the points. At the outset, the present value of the FX swap contract is usually arranged to be zero.

The same conditions prevail with an FX swap as with an outright forward—a trader who pays the points in the forward also pays them in the FX swap; a trader who earns the points in the forward also earns them in the FX swap.

For most currencies, swap points are carried to the fourth decimal place. A dollar-swissie swap quoted at 244-221 means that the dealer will buy the dollar forward at his spot bid rate less 0.0244 (in Swiss francs), and sell the dollar forward at his spot offer rate less 0.0221 (in Swiss francs), yielding an (additional) spread of 23 points (or 0.0023).

The FX swap is the difference between the spot and the outright forward (or the difference between the two outright forwards). When you trade an FX swap you are trading the interest rate differential between the two currencies. The FX swap is a very flexible and convenient instrument that is used for a variety of funding, hedging, position management, speculation, and other purposes. FX swaps are extremely popular among OTC interbank dealers, and now account for nearly half of total turnover in the U.S. OTC foreign exchange market. Among its uses are those described in Box 5-3:

**Box 5-3**

### Some Uses of FX Swaps

Managing positions and changing settlement dates. FX swaps can be very helpful in managing day-to-day positions. Of particular convenience and interest to professional market making and dealing institutions are the “spot-next” swap and the “tom-next” swap, which are used by traders to roll over settlements and to balance maturing buys and sells of particular currencies in their books. A dealer who knows, say June 1, that he has to pay out a certain

(continued on page 42)
currency on June 3, may find it convenient or profitable to extend the settlement for a day, for example, when he may be scheduled to receive balances of that currency. The dealer can enter into a “spot-next” swap on the deal date, June 1, and extend the June 3 settlement to June 4. Alternatively, on June 2, the day before the June 3 settlement, the dealer might arrange a “tom-next” swap, to extend that settlement until June 4, which is the spot settlement date for June 2, and a more liquid market. The cost of these one-day swaps would reflect the points (the value of one day’s interest differential), or “cost of carry,” which would be added to or subtracted from the spot rate. If it then looked as though a June 4 settlement would be difficult, the dealer might roll over the transaction for another day, or longer.

The interest rate differential is also important in calculating “pre-spot” rates—“value tomorrow” transactions, which are settled one day before spot and “cash,” which are settled two days before spot, or on the deal date.

To calculate (approximate) “pre-spot” rates, you work backwards. Thus, assume that dollar-swissie were trading spot at 1.5000-10. Assume that the points for a “tom-next” swap were 3/5, reflecting one day’s interest rate differential—the price of extending settlement from day 2 to day 3. To calculate a “value tomorrow” quote—shifting settlement from day 3 to day 2, you would turn the points around (to 5/3) and reverse the sign (in this case subtract them from, rather than add them to, the spot rate), for a quote of 1.4995-97. (In shifting a settlement forward, the higher interest rate currency moves to discount; in shifting backward to “cash” or “value tomorrow,” the higher interest rate currency moves to premium.)

Hedging interest rate differential risk. A dealer, for example, who has agreed to buy pounds sterling one year forward faces both an exchange rate risk (that the exchange rate may change) and an interest rate differential risk (that the interest rate differential on which the transaction was priced may change). The dealer can offset the exchange rate risk by selling sterling spot (to offset the forward purchase), but he would still have an interest rate differential risk. That risk can be offset in two ways: either by borrowing and investing in the off-shore deposit (Euro-currency) markets, or by entering into a new swap (an “unwind”) that is the opposite of his outstanding position (that is, the trader can enter into a buy/sell sterling swap for a one-year period to offset the position resulting from his forward sterling purchase and spot sterling sale). If neither of the two interest rates nor the spot rate has changed between the time of the trader’s initial forward purchase of sterling and the time when the trader’s hedging activities are put in place, the trader can cover risk in either the FX swap market or the offshore deposit market—the trader has a “perfect” hedge—but the swap may be carried “off-balance-sheet” and thus may be “lighter” on the trader’s balance sheet than the borrowing and lending.

Speculating on interest rate differentials. A dealer who expects an interest rate differential to widen would enter into an FX swap in which the dealer pays the swap points now (when the differential is small), and—after the interest rate differential has widened—would then enter
into another FX swap in the opposite direction (an unwind), in which case the trader would earn more swap points from the wider differential than he is paying on the initial swap. A trader who expects interest rate differentials to narrow would do the reverse—arrange swaps in which he earns the swap points now, when the differential is wide, and pays the swap points later, after the differential narrows.

Arbitraging the foreign exchange market and the interest rate market. When the two markets are in equilibrium, a dealer may be more or less indifferent whether he invests through the offshore deposit market (borrowing/lending currencies) or through the foreign exchange market (FX swaps). But there are times when swap points in the foreign exchange market are not precisely equivalent to interest rate differentials in the offshore deposit market, and arbitrageurs can use FX swaps together with deposit borrowing and lending operations to fund in the lower-cost market and invest in the higher-return market.

**Calculating FX Swap Points**

A market maker will calculate swap points on the basis of borrowing and lending rates in the offshore deposit markets:

A. Bid Side Swap Points = Spot Rate \[ \frac{1 + (\text{ODBRTC} \times \text{Swap Days})}{360 \text{ or } 365} - 1 \]

B. Offer Side Swap Points = Spot Rate \[ \frac{1 + (\text{ODLRTC} \times \text{Swap Days})}{360 \text{ or } 365} - 1 \]

where ODBRTC = offshore deposit borrowing rate in terms currency, ODLRTC = offshore deposit lending rate in base currency, ODBRBC = Euro borrow rate in base currency, and ODLRBC = offshore deposit lending rate in base currency. Assume that offshore deposit $ rates = 5 - 5.25, offshore deposit DEM rates = 6.25 - 6.50, the swap period = 62 days, and the spot rate = DEM 1.600 per dollar. Then, swap points can be calculated as:

A. Bid Side Points = 1.600 \[ \frac{1 + (0.0625 \times 62)}{360} - 1 = 28 \]

B. Offer Side Points = 1.600 \[ \frac{1 + (0.0650 \times 62)}{360} - 1 = 41 \]

(continued on page 44)
A currency swap is structurally different from the FX swap described above. In a typical currency swap, counterparties will (a) exchange equal initial principal amounts of two currencies at the spot exchange rate, (b) exchange a stream of fixed or floating interest rate payments in their swapped currencies for the agreed period of the swap, and then (c) re-exchange the principal amount at maturity at the initial spot exchange rate. Sometimes, the initial exchange of principal is omitted. Sometimes, instead of exchanging interest payments, a “difference check” is paid by one counterparty to the other to cover the net obligation.

The currency swap provides a mechanism for shifting a loan from one currency to another, or shifting the currency of an asset. It can be used, for example, to enable a company to borrow in a currency different from the currency it needs for its operations, and to receive protection from exchange rate changes with respect to the loan.

The currency swap is closely related to the interest rate swap. There are, however, major differences in the two instruments. An interest rate swap is an exchange of interest payment streams of differing character (e.g., fixed rate interest for floating), but in the same currency, and involves no exchange of principal. The currency swap is in concept an interest rate swap in more than one currency, and has existed since the 1960s. The interest rate swap became popular in the early 1980s; it subsequently has become an almost indispensable instrument in the financial tool box.

Currency swaps come in various forms. One variant is the fixed-for-fixed currency swap, in which the interest rates on the periodic interest payments of the two currencies are fixed at the outset for the life of the swap. Another variant is the fixed-for-floating swap, also called cross-currency swap, or currency coupon swap, in which the interest rate in one currency is floating (e.g., based on LIBOR) and the interest rate in the other is fixed. It is also possible to arrange floating-for-floating currency swaps, in which both interest rates are floating.

1. Purposes of Currency Swaps

The motivations for the various forms of currency swap are similar to those that generate a demand for interest rate swaps. The incentive may arise from a comparative advantage that a borrowing company has in a particular currency or capital market. It may result from a company's desire to diversify and spread its borrowing around to
A foreign exchange or currency option contract gives the buyer the right, but not the obligation, to buy (or sell) a specified amount of one currency for another at a specified price on (in some cases, on or before) a specified date. Options are unique in that the right to execute will be exercised only if it is in the holder's interest to do so. That differs from a forward contract, in which the parties are obligated to execute the transaction on the maturity date, and it differs from a futures contract, in which the parties are obligated, in principle, to transact at maturity, but that obligation can be bought out and liquidated before the maturity or delivery date.

A call option is the right, but not the obligation, to buy the underlying currency, and a put option is the right, but not the obligation, to sell the underlying currency. All currency option trades involve two sides—the purchase of one currency and the sale of another—so that a put to sell pounds sterling for dollars at a certain price is also a call to buy dollars for pounds sterling at that price. The purchased currency is the call side of the trade, and the sold currency is the put side of the trade. The party who purchases the option is the holder or buyer, and the party who creates the option is the seller or writer. The price at which the underlying currency may be bought or sold is the exercise, or strike, price. The option premium is the price of the option that the buyer pays to the writer. In exchange for paying the option premium up front, the buyer gains insurance against adverse movements in the underlying spot exchange rate.
while retaining the opportunity to benefit from favorable movements. The option writer, on the other hand, is exposed to unbounded risk—although the writer can (and typically does) seek to protect himself through hedging or offsetting transactions.

In general, options are written either “European style,” which may be exercised only on the expiration date, or “American style,” which may be exercised at any time prior to, and including, the expiration date. The American option is at least as valuable as the European option, since it provides the buyer with more opportunities, but is analytically more complex. American calls on the higher interest rate currency are likely to be more valuable than the equivalent European option. The bulk of trading in the OTC interbank market consists of European options, while American options are standard on some of the exchanges.
The option is one of the most basic financial instruments. All derivatives, including the various derivative financial products developed in recent years—the many forms of forwards, futures, swaps, and options—are based either on forwards or on options; and forwards and options, notwithstanding their differences, are related to each other. A forward can be created synthetically from a combination of European options: Buying a call option and selling a put option (long a call, short a put) on a currency with strike prices at the forward rate provides the same risk position as buying a forward contract on that currency. At expiration, the payoff profiles of the forward and the synthetic forward made up of the two options would be the same: The holder would receive the same payoff whether he held the forward or the combination of two options.

As a financial instrument, the option has a long history. But foreign exchange options trading first began to flourish in the 1980s, fostered by an international environment of fluctuating exchange rates, volatile markets, deregulation, and extensive financial innovation. The trading of currency options was initiated in U.S. commodity exchanges and subsequently was introduced into the over-the-counter market. However, options still account for only a small share of total foreign exchange trading.

An over-the-counter foreign exchange option is a bilateral contract between two parties. In contrast to the exchange-traded options market (described later), in the OTC market, no clearinghouse stands between the two parties, and there is no regulatory body establishing trading rules.

Also, in contrast to the exchange-traded options market, which trades in standardized contracts and amounts, for a limited number of currency pairs, and for selected maturity dates, an OTC option can be tailored to meet the special needs of an institutional investor for particular features to satisfy its investment and hedging objectives. But while OTC options...
contracts can be customized, a very large share of the OTC market consists of generic, or “plain vanilla,” options written for major currencies in standard amounts and for even dates.

OTC options are typically written for much larger amounts than exchange-traded options—an average OTC option is $30-$40 million equivalent—and a much broader range of currencies is covered. The volume of OTC options is far greater than that of exchange-traded options; indeed, the OTC market accounts for about four-fifths of the total foreign exchange options traded in the United States.

The two options markets, OTC and exchange-traded, are competitors to some extent, but they also complement each other. Traders use both markets in determining the movement of prices, and are alert to any arbitrage opportunities that may develop between the two markets. Dealers in the OTC market may buy and sell options on the organized exchanges as part of the management of their own OTC positions, hedging or laying off part of an outstanding position in an exchange market.

The Pricing of Currency Options
It is relatively easy to determine the value of a European option at its expiration. The value of a European option at expiration is its intrinsic value—the absolute amount by which the strike price of the option is more advantageous to the holder that the spot exchange rate. If at expiration the strike price is more advantageous than the spot rate of the underlying, the option is “in the money”; if the difference between the strike price and the spot rate is zero, the position is “at the money”; if the strike price is less advantageous than the spot rate, the option is “out of the money.”

Determining the price of an option prior to expiration, on the other hand, is much more difficult. Before expiration, the total value of an option is based, not only on its intrinsic value (reflecting the difference between the strike price and the then current exchange rate), but also on what is called its time value, which is the additional value that the market places on the option, reflecting the time remaining to maturity, the forecast volatility of the exchange rate, and other factors.

Time value is not linear. A one-year option is not valued at twice the value of a six-month
option. An “at-the-money” option has greater
time value than an “in-the-money” or “out-of-
the-money” option. Accordingly, options—
unlike forwards and futures—have convexity;
that is, the change in the value of an option for
a given change in the price of the underlying
asset does not remain constant. This makes
pricing options much more complex than
pricing other foreign exchange instruments.

A major advance in the general theory of
options pricing was introduced by Professors
Black and Scholes in 1973. Their work,
which was subsequently adapted for foreign
exchange options, showed that under certain
restrictive assumptions, the value of a
European option on an underlying currency
depends on six factors: 1) the spot exchange
rate; 2) the interest rate on the base (or
underlying) currency; 3) the interest rate on
the terms currency; 4) the strike price at
which the option can be exercised; 5) the time
to expiration; and 6) the volatility of the
exchange rate.

Volatility, a statistical measure of the
tendency of a market price—in this case, the
spot exchange rate—to vary over time, is the
only one of these variables that is not known
in advance, and is critically important in
valuing and pricing options. Volatility is the
annualized percentage change in an exchange
rate, in terms of standard deviation (which is
the most widely used statistical measurement
of variation about a mean). The greater the
forecast volatility, the greater the expected
future movement potential in the exchange
rate during the life of the option—i.e., the
higher the likelihood the option will move
“in-the-money,” and so, the greater the value
(and the cost) of the option, be it a put or a
call. (With zero volatility, the option should
cost nothing.)

If the one-year forward dollar-Swiss
franc exchange rate is CHF 1.6000 = $1, and the
volatility of a one-year European option price is
forecast at 10 percent, there is implied the
expectation, with a 68 percent probability, that
one year hence, the exchange rate will be within
CHF 1.6000 per dollar plus or minus 10
percent—that is, between CHF 1.4400 and CHF
1.7600 per dollar.

There are different measurements of volatility:
- Historical volatility is the actual volatility, or
variance, of an exchange rate that occurred
during some defined past time frame. This can
be used as an indication or guide to future
movements in the exchange rate.
- Future volatility is the expected variance in the
exchange rate over the life of the option, and
must be forecast.
- Implied volatility is the variance in an
exchange rate that is implied by or built into
the present market price of an option—thus, it
is the market’s current estimate of future
movement potential as determined by supply
and demand for the option in the market.

Implied volatility is a critical factor in options
pricing. In trading options in the OTC interbank
market, dealers express their quotes and execute
their deals in terms of implied volatility. It is the
metric, or measuring rod—dealers think and
trade in terms of implied volatilities and make
their predictions in that framework, rather than in
terms of options prices expressed in units of a
currency (which can change for reasons other than
volatility changes—e.g., interest rates). It is easier
to compare the prices of different options, or
compare changes in market prices of an option
over time, by focusing on implied volatility and
quoting prices in terms of volatility. (For similar
reasons, traders in outright forwards deal in terms
of discounts and premiums from spot, rather than
in terms of actual forward exchange rates.)
If market quotes and trades are to be made in terms of implied volatilities (or vols), all traders must use the same concept and conventions for computing volatility, so that they are all speaking the same language. The technique used in the market is to solve the Black-Scholes formula backwards—to take the price of an option in the market as given and calculate the volatility that is implied by that market price. Traders use this Black-Scholes-based computation of implied volatility as a way of communicating and understanding each other, even though they know that it has certain limitations. For example, they know (and take into account) that the technique inherently incorporates into the estimate of “implied volatility” all sources of mispricing, data errors, effects of bid-offer spreads, etc. They also know that the calculation assumes that all of the rigorous assumptions in the Black-Scholes theoretical pricing model apply, whereas in the market in which they are operating in the “real” world, these assumptions may not all apply.

**Delta.** Another important parameter for assessing options risk, also calculated from the Black-Scholes equation, is the delta, which measures how much the price of an option changes with a small (e.g., one percent) change in the value of the underlying currency.

Very importantly, the delta is also the hedge ratio, because it tells an option writer or a holder at any particular moment just how much spot foreign exchange he must be long or short to hedge an option position and eliminate (at least for that moment) the spot position risk.

Thus, if a trader sold a European call option on marks/put option on dollars with the face amount of $10 million, with the strike price set at the forward rate (an “at-the-money forward”), the chances at that moment are about 50-50 that the option will rise in value and at expiration be exercised, or fall in value and at expiration be worthless. If the option at that moment had a delta of 0.50, the trader could hedge, or neutralize, his option risk by taking an opposite spot position (purchase of marks/sale of dollars) equal to 50 percent of the option’s face amount, or $5 million. This is called a “delta hedge.” (If the strike price were “in-the-money,” the delta would be between 0.50 and 1.00; if the strike price were “out-of-the-money,” the delta would be between 0 and 0.50. At expiration, delta ends up either 0 (out-of-the-money and won’t be exercised), or 1.00 (in the money and will be exercised).

Most option traders routinely “delta hedge” each option they purchase or write, buying or selling in the spot or forward market an amount that will fully hedge their initial exchange rate risk. Subsequently, as the exchange rate moves up or down, the option dealer will consider whether to maintain a neutral hedge by increasing or reducing this initial position in the spot or forward market.

However, the delta, or hedge ratio, whether it starts out at 0.50 or at some other number, will change continually, not only with each significant change in the exchange rate, but also with changes in volatility, or changes in interest rates, and, very importantly, delta will change with the passage of time. An option with a longer time to run is more valuable than an option with a shorter time to run. Thus, new calculations will continually be required as conditions change, to determine the new delta and the change in spot or forward foreign exchange position needed to maintain a neutral hedge position.
Delta Hedging

Option dealers who are actively trading in the market usually enter into an initial hedge (delta hedge) for each option each time they buy or write a put or a call.

Thus, if the delta is 0.50, the writer (seller) of a GBP 10 million call option might buy GBP 5 million spot and the buyer of the option sell GBP 5 million, as part of the option transaction.

At that point, both parties are hedged—the values of their option positions are exactly the same as the values of their spot hedges, but in opposite directions. Thus, if the price of the underlying currency moves up or down by a very small amount (say less than 1%), the option writer (and the option buyer) will gain or lose from the value of his spot hedge position an amount which would approximately offset the loss or gain in the value of the option.

However, the delta and the need for a spot hedge position change if the exchange rate changes and the option moves “into” or “out of” the money. If the price of the underlying currency moves up, and the value of the call option moves up, the delta moves up to, say, 0.60, so that to stay fully hedged the writer of the option has to buy more spot GBP, and the buyer of the option has to sell more spot GBP.

Option dealers have to keep a very close eye on exchange rate movements and decide, with each significant move up or down, whether to adjust delta hedges. In very choppy markets, it can be very expensive to delta hedge every movement up or down. For example, if a dealer wrote an option and the exchange rate bounced up and down (that is, had high volatility) so that the delta moved numerous times during the life of the option between, say, 0.45 and 0.55, the dealer could spend far more for hedging than for the premium that he received for writing the option—and incur a large overall loss even though the option might end up “out-of-the-money” and not be exercised.

Whether the option would result in a net gain or net loss for the option writer, assuming every exchange rate were delta hedged efficiently, would depend on whether the writer correctly forecast the volatility of the underlying currency, and priced the option on the basis of that volatility.

If the actual volatility of the currency over the life of the option turned out to be exactly the same as the volatility used in calculating the original premium, the delta hedge losses would (in principle) equal the original premium received, and the option writer would break even. If actual volatility turned out to be greater than forecast, the option writer would lose; if actual volatility were less than forecast, the option writer would gain. (This is not a surprising outcome, since an option is a bet on volatility—greater-than-anticipated volatility is beneficial to an option holder, and harmful to an option writer; less-than-anticipated volatility is the other way around.)

Delta hedging is a very important feature of the currency options market. It allows an important element of options risk to be transferred to the much larger and more liquid spot market, and thus allows options traders to quote a much broader range of options, and to quote narrower margins.
Put-Call Parity

“Put-call parity” says that the price of a European put (or call) option can be deduced from the price of a European call (or put) option on the same currency, with the same strike price and expiration. When the strike price is the same as the forward rate (an “at-the-money” forward), the put and the call will be equal in value. When the strike price is not the same as the forward price, the difference between the value of the put and the value of the call will equal the difference in the present values of the two currencies.

Arbitrage assures this result. If the “put-call parity” relationship did not hold, it would pay to create synthetic puts or calls and gain an arbitrage profit. If, for example, an “at-the-money forward” call option were priced in the market at more than (rather than equal to) an “at-the-money forward” put option for a particular currency, a synthetic call option could be created at a cheaper price (by buying a put at the lower price and buying a forward at the market price). Other synthetics can be produced by other combinations (e.g., buying a call and selling a forward to produce a synthetic put; buying a call and selling a put to create a synthetic long forward; or selling a call and buying a put to create a synthetic short forward).

The “put-call parity” is very useful to options traders. If, for example, puts for a particular currency are being traded, but there are no market quotes for the corresponding call, traders can deduce an approximate market price for the corresponding call.

How Currency Options are Traded

The OTC options market has become a 24-hour market, much like the spot and forward markets, and has developed its own practices and conventions. Virtually all of the major foreign exchange dealer institutions participate as market makers and traders. They try to stay fully abreast of developments, running global options books that they may pass from one major center to another every eight hours, moving in and out of various positions in different markets as opportunities arise. Some major dealers offer options on large numbers of currency pairs (fifty or more), and are flexible in tailoring amounts and maturities (from same day to several years ahead). They can provide a wide array of different structures and features to meet customer wishes.

A professional in the OTC interbank options market asking another professional for a quote must specify more parameters than when asking for, say, a spot quote. The currency pair, the type of option, the strike price, the expiration date, and the face amount must be indicated. Dealers can do business with each other directly, by telephone or (increasingly) via electronic dealing system, which makes possible a two-way recorded conversation on a computer screen. Also, they can deal through an OTC (voice) broker. Among these dealers and brokers, quotes are presented in terms of the implied volatility of the option being traded.

As in other foreign exchange markets, a market maker is expected to give both a bid—the volatility at which he is prepared to buy an option of the specified features—and an offer—the volatility at which he is prepared to sell such an option.

For example, an interbank dealer, Jack from Bank X, might contact a market maker, Jill from Bank Z, identify himself and his institution and ask for a quote:

Jack: “Three month 50-delta dollar put/yen call on 20 dollars, please.”
Jill: “14.50-15.”
Jack: “Yours at 14.50.”
Jill: “Done. I buy European three-month 50-delta dollar put/yen call on 20 dollars.”
After this commitment to the trade, details ("deets") would then be worked out and agreed upon with respect to the exact expiration date, the precise spot rate, the exact strike price, and option premium. Customarily, in trades between dealers, there would be an offsetting transaction in spot or forward trade, in the opposite direction to the option, to provide both parties with the initial delta hedge.

Note that Jack and Jill specified both currencies—"dollar put/yen call." In foreign exchange options, since a call allowing you to buy yen for dollars at a certain price is also a put allowing you to sell dollars for yen at that price, it helps to avoid confusion if both formulations are mentioned.

**Options Combinations and Strategies**

Combinations of options are used among the professionals for many purposes, including taking directional views on currencies—anticipating that a particular currency will move up or down—as well as taking volatility views on currencies—anticipating that a particular exchange rate will vary by more or by less than the market expects. Among the options combinations that are currently most widely used by traders in the OTC market are the following:

- **A straddle** consists of one put and one call with the same expiration date, face amount, and strike price. The strike price is usually set at the forward rate—or "at-the-money forward" (ATMF)—where the delta is about 0.50. A long straddle gains if there is higher than forecast volatility, regardless of which of the two currencies in the pair goes up and which goes down—and any potential loss is limited to the cost of the two premiums. By the same token, a short straddle gains if there is less than expected volatility, and the potential gain is limited to the premiums. Thus, a trader buys volatility by buying a straddle, and sells volatility by selling a straddle. Straddles account for the largest volume of transactions in interbank trading.

- A **strangle** differs from a straddle in that it consists of a put and a call at different strike prices, both of which are "out-of-the-money," rather than "at-the-money." Often the strike prices are set at 0.25 delta. It is a less aggressive position than the straddle—a long strangle costs less to buy, but it requires a higher volatility (relative to market expectations of volatility) to be profitable.

- A **risk reversal** is a directional play, rather than a volatility play. A dealer exchanges an out-of-the-money (OTM) put for an OTM call (or vice versa) with a counterparty. Since the OTM put and the OTM call will usually be of different values, the dealer pays or receives a premium for making the exchange. The dealer will quote the implied volatility differential at which he is prepared to make the exchange. If, for example, market expectations that the dollar will fall sharply against the Swiss franc are much greater than market expectations that the dollar will rise sharply against the Swiss franc, the dealer might quote the price of dollar-swissie risk reversals as follows: "For a three-month 0.25-delta risk reversal, 0.6 at 1.4 swissie calls over." That means the dealer is willing to pay a net premium of 0.6 vols (above the current implied ATM volatility) to buy a 0.25-delta OTM Swiss franc call and sell a 0.25-delta OTM Swiss franc put against the dollar, and he wants to earn a net premium of 1.4 vols (above the current implied ATM premium) for the opposite transaction. The holder of a risk reversal who has sold an OTM put and bought an OTM call will gain if the call is exercised, and he will lose if the put is exercised—but unlike the holder of a long straddle or long strangle (where the maximum loss is the premium paid), on the put he has sold his potential loss is unbounded.
FOREIGN EXCHANGE OPTIONS GALORE

The array of foreign exchange options available in the OTC market to dealers and the broader market of customers is almost endless, and new forms are being created all the time. Naturally, the following list is not comprehensive.

- **Multi-currency options** give the right to exchange one currency, say dollars, for one of a number of foreign currencies at specified rates of exchange.
- **Split fee options** enable the purchaser to pay a premium up front, and a “back fee” in the future to obtain the foreign currency if the exchange rate moves in favor of the option.
- **Contingent options** involve a payoff that depends, not only on the exchange rate, but also on such conditions as whether the firm buying the option obtains the contract for which it is tendering, and for which the option was needed.
- There are a large number of options with **reduced or zero cash outlay** up front—which is made possible by combinations (buying one or more options and selling others) that result in a small or zero net initial outlay. One example is the **range forward or cylinder option**, which gives the buyer assurance that not more than an agreed maximum rate will be paid for needed foreign currency, but requires that the buyer agree he will pay no less than a stipulated (lower) minimum rate. Another example is the **conditional forward**, in which the premium is paid in the future but only if the exchange rate is below a specified level. A third example is the **participating forward**, in which the buyer is fully protected against a rise in the exchange rate, but pays a proportion of any decrease in the exchange rate. Such options—and there are any number of varieties—are popular since the buyer pays for his option by providing another option, rather than by paying cash, giving the **appearance** (which can be misleading) of cost-free protection, or the proverbial free lunch.
There is the all-or-nothing, or binary, option, where, if the exchange rate is beyond the strike price at expiration, there is a fixed payout, and the amount is not affected by the magnitude of the difference between the underlying and the strike price.

There are various forms of path dependent options, in which the option’s value is determined, not simply by the exchange rate at the expiration of the option, but partly or exclusively by the path that the exchange rate took in arriving there. There are barrier options, in which, for example, the option expires worthless if the exchange rate hits some pre-agreed level, or, alternatively, in which the option pays off only if some pre-specified exchange rate is reached prior to expiration. There are Bermuda options (somewhere between American and European options) in which rights are exercisable on certain specified dates. There are Asian, or average rate, options, which pay off at maturity on the difference between the strike price and the average exchange rate over the life of the contract. There are look back options, or “no regrets” options, which give the holder the retroactive right to buy (sell) the underlying at its minimum (maximum) within the look back period. There are down-and-out options, knock-out options, and kick-out options, that expire if the market price of the underlying drops below a predetermined (out strike) price, and down-and-in options etc., that take effect only if the underlying drops to a predetermined (in strike) price.

Compound options are options on options, and chooser options allow the holder to select before a certain date whether the option will be a put or a call.

There are non-deliverable currency options (as there are non-deliverable forwards) which do not provide for physical delivery of the underlying currency when the option is exercised. If exercised, the option seller pays the holder the “in the money” amount on the settlement date in dollars or other agreed settlement currency.

Other permutations include models developed in-house by the major dealers to meet individual customers’ needs, and any number of customized arrangements that attach or embed options as part of more complex transactions.
### Main Contracts in the U.S. Foreign Exchange Market

<table>
<thead>

In the U.S. exchanges, a foreign exchange futures contract is an agreement between two parties to buy/sell a particular (non-U.S. dollar) currency at a particular price on a particular future date, as specified in a standardized contract common to all participants in that currency futures exchange. (See Box 6-1 on the evolution of foreign exchange futures.) When entering into a foreign exchange futures contract, no one is actually buying or selling anything—the participants are agreeing to buy or sell currencies on pre-agreed terms at a specified future date if the contract is allowed to reach maturity, which it rarely does.

A foreign exchange futures contract is conceptually similar to an outright forward foreign exchange contract, in that both are agreements to buy or sell a certain amount of a certain currency for another at a certain price on a certain date. However, there are important structural and institutional differences between the two instruments:

- Futures contracts are traded through public “open outcry” in organized, centralized exchanges that are regulated in the United States by the Commodity Futures Trading Commission. In contrast, forward contracts are traded “over-the-counter” in a market that is geographically dispersed, largely self-regulated, and subject to the ordinary laws of commercial contracts and taxation.

- Futures contracts are standardized in terms of the currencies that can be traded, the amounts, and maturity dates, and they are subject to the trading rules of the exchange with respect to daily price limits, etc. Forward contracts can be customized to meet particular customer needs.

- Futures contracts are “marked to market” and adjusted daily; there are initial and maintenance margins and daily cash settlements. Forward contracts do not require any cash payment until maturity (although a bank writing a forward contract may require collateral). Thus, a futures contract can be viewed as a portfolio or series of forwards, each covering a day or a longer period between cash settlements.

- Futures contracts are netted through the clearinghouse of the exchange, which receives the margin payments and guarantees the performance of both the buyer and the seller in every contract. Forward contracts are made directly between the two parties, with no clearinghouse between them.

The differences between the two instruments are very important. The fact that futures contracts are channeled through a clearinghouse and

**Table Note:**
- **Main Instruments:** Exchange-traded market

**ALL ABOUT...**
Development of Foreign Currency Futures

Foreign exchange futures—and financial futures generally—were introduced by the International Monetary Market (IMM) of the Chicago Mercantile Exchange in 1972, at the time of the breakdown of the Bretton Woods system of par value exchange rates. Prior to that time, there were organized exchange markets only for commodity futures, which first developed in the mid-1800s in the United States for trading in agricultural commodities such as wheat and pork bellies, imported foodstuffs such as coffee and cocoa, and industrial commodities such as copper and oil.

The IMM moved to apply the same organizational and trading techniques used in the commodity markets to a range of financial instruments, including foreign currency futures. This approach spread to other exchanges in the United States and abroad. A number of financial futures contracts are now traded, not only for currencies, but also for stock indexes and interest rates. In foreign exchange, the futures market now provides an alternative channel through which individual investors and businesses can take positions in foreign currencies for hedging or speculating.

In addition to the IMM of the Chicago Mercantile Exchange, the exchanges in the United States that trade foreign exchange futures are the Mid-America Commodity Exchange, which is a subsidiary of the Chicago Board of Trade; the Financial Instrument Exchange (Finex), which is a subsidiary of the New York Board of Trade (formerly Cotton Exchange); and the Philadelphia Board of Trade. In the United States, the Commodity Futures Trading Commission (CFTC) has jurisdiction over futures contracts, including foreign exchange futures.

The system of trading in futures markets is not greatly different from the practices introduced in the United States in the middle of the last century. There is a designated location (a “pit”) where a large number of traders (“locals” who buy and sell for themselves, and “pit brokers” who also execute trades for others) communicate, often by hand signals, and complete their deals according to established rules, with all bids and offers announced publicly. Some new practices have been introduced. An “exchange for physicals” (EFP) market provides for trading futures contracts outside exchange hours, with prices for foreign exchange futures determined by interest parity from the spot market, which trades on a 24-hour day basis. Also, the Chicago Mercantile Exchange, working with others, has developed a system called “Globex” to provide for trading futures contracts when a futures exchange is closed.

“marked to market” daily means that credit risk is reduced. The fact that the clearinghouse is guaranteeing the performance of both sides also means that a contract can be canceled (or “killed”) simply by buying a second contract that reverses the first and nets out the position. Thus, there is a good “secondary market.” In a forward contract, if a holder wanted to close or reverse a position, there would have to be a second contract, and if the second contract is arranged with a different counterparty from the first, there would be two contracts and two counterparties, with credit risk on both.

Because of the differences in the two markets, it is not hard to understand why the
two markets are used differently. Futures contracts seldom go to maturity—less than two percent result in delivery—and are widely used for purposes of financial hedging and speculation. The ease of liquidating positions in the futures market makes a futures contract attractive for those purposes. The high degree of standardization in the futures market means that traders need only discuss the number of contracts and the price, and transactions can be arranged quickly and efficiently.

Forward contracts are generally intended for delivery, and many market participants may need more flexibility in setting delivery dates than is provided by the foreign exchange futures market, with its standard quarterly delivery dates and its one-year maximum maturity. Transactions are typically for much larger amounts in the forward market—millions, sometimes many millions, of dollars—while most standardized futures contracts are each set at about $100,000 or less, though a single market participant can buy or sell multiple contracts, up to a limit imposed by the exchange. Also, forward contracts are not limited to the relatively small number of currencies traded on the futures exchanges.

The foreign currency futures market provides, to some extent, an alternative to the OTC forward market, but it also complements that market. Like the forward market, the currency futures market provides a mechanism whereby users can alter portfolio positions other than through the alternative of the cash or spot market. It can accommodate both short and long positions, and it can be used on a highly leveraged basis for both hedging and speculation. It thus facilitates the transfer of risk—from hedgers to speculators, or from speculators to other speculators.

In addition, the foreign currency futures market contributes to the “information” and the “price discovery” functions of markets—although the contribution may be moderate in the case of foreign exchange, since the estimated total turnover of currency futures markets is far below that of the market in outright forwards.

As in the case of forwards, prices in the foreign currency futures market are related to the spot market by interest rate parity. The theoretical price of a forward contract will be the spot exchange rate plus or minus the net cost of financing (the cost of carry), which is determined by the interest rate differential between the two currencies. In the case of futures, where there are margin requirements, daily marking to market, and different transactions costs, the price should presumably reflect those differences. In practice, however, the market prices of forwards and futures seem not to diverge very much for relatively short-term contracts.

Quotes for Foreign Currency Futures

Figure 6-2 reports data from The New York Times, showing the foreign currency futures quotes on April 27, 1998—an arbitrarily chosen date—for contracts trading on the International Money Market (IMM) of the Chicago Mercantile Exchange; including the Japanese yen, the Deutsche mark, the Canadian dollar, the British pound, and the Swiss franc. (With the introduction of the euro in 1999, a number of the contracts will be changed.) Contracts for each currency are of a standard size—e.g., for the pound sterling the face amount is £62,500; for the Deutsche mark it is DEM 125,000. There are trading rules—for example, there is a minimum allowable price move between trades, and a maximum allowable price movement in a day. The
Exchange-traded currency options, like exchange-traded futures, utilize standardized contracts—respect to the amount of the underlying currency, the exercise price, and the expiration date. Transactions are cleared through the clearinghouses of the exchanges on which they are traded, and the clearinghouses guarantee each party against default of the other. The option buyer—who has no further financial obligation after he has paid the premium—is not required to make margin payments. The option writer—who has all of the financial risk—is required to put up initial margin and to make additional (maintenance) margin payments if the market price moves adversely to his position.

In the United States, exchange-traded foreign exchange options were introduced in 1982. Options on foreign currencies presently are traded on the Philadelphia Stock Exchange (PHLX) and the Chicago Mercantile Exchange (CME). Options on a U.S. dollar index and on the ECU are traded on Finex, the financial division of the New York Cotton Exchange. The Securities and Exchange Commission (SEC) has jurisdiction over options on foreign currencies traded on national securities exchanges, while the Commodity Futures Trading Commission (CFTC) regulates options on foreign currency futures and options on foreign currencies traded on exchanges that are not securities exchanges. Abroad, options

---

**2. EXCHANGE-TRADED CURRENCY OPTIONS**

Exchange-traded currency options, like exchange-traded futures, utilize standardized contracts—with respect to the amount of the underlying currency, the exercise price, and the expiration date. Transactions are cleared through the clearinghouses of the exchanges on which they are traded, and the clearinghouses guarantee each party against default of the other. The option buyer—who has no further financial obligation after he has paid the premium—is not required to make margin payments. The option writer—who has all of the financial risk—is required to put up initial margin and to make additional (maintenance) margin payments if the market price moves adversely to his position.

Note that the futures exchange rates of all of the contracts are quoted in terms of the value of the foreign currency as measured in U.S. dollars, and premiums are quoted in U.S. cents per mark or pound—that is, in “direct” or “American” terms. This technique is consistent with long-standing practice in commodity exchanges for quoting futures contracts for agricultural and industrial products. But it differs from conventions in other parts of the exchange market—a Swiss franc forward would be priced at, say, “1.6000” (in CHF per dollar) while a Swiss franc future would be priced at the reciprocal, or “0.6250” (in dollars per CHF).
It is important to note how all of the main foreign exchange instruments described in Chapters 5 and 6 are linked to each other, creating a comprehensive network within which the forces of arbitrage can induce consistent rate relationships and pooled liquidity, which can benefit the various sectors of the market.

These linkages are summarized in Box 6-2.

**3. Linkages**

The CME trades options on the same eight currencies as the PHLX, but trades options on futures, rather than on spot, or cash. That is to say, at the CME a buyer can purchase a contract that provides the right, but not the obligation, for example, to go long on an exchange-traded foreign exchange futures contract at a strike price stated in terms of a different currency. If an option on foreign currency futures is exercised, any profit can be immediately recognized by closing out the futures position through an offsetting transaction.

All CME options on foreign exchange futures are American style—exercisable on or before the maturity date. These CME options contracts are the same size as IMM futures standardized contracts—each CME option represents the right to go long or short a single IMM foreign exchange futures contract. Figure 6-3 shows the quotes for call and put options on April 27, 1998.

**BOX 6-2**

**Linkages Between Main Foreign Exchange Instruments in Both OTC and Exchange-Traded Markets**

- **SPOT** (settled two days after deal date, or T+2) = Benchmark price of a unit of the base currency expressed in a variable amount of the terms currency.

- **Pre-Spot:** **VALUE TOMORROW** (settled one day after deal date, or T+1) = Price based on spot rate adjusted for the value for one day of the interest rate differential between the two currencies. (Higher interest rate currency trades at a *premium* from spot.)

(continued on page 66)
The Foreign Exchange Market in the United States 65

main instruments: exchange-traded market

(continued from page 65)

- Pre-Spot: CASH (settled on deal date, or T+0) = Price based on spot rate adjusted for the value for two days of the interest rate differential between the two currencies. (Higher interest rate currency trades at a premium from spot.)

- OUTRIGHT FORWARD = Price based on spot rate adjusted for the value of the interest rate differential between the two currencies for the number of days of the forward. (Higher interest rate currency trades at a forward discount from spot.)

- FX SWAP = One spot transaction plus one outright forward transaction for a given amount of the base currency, going in opposite directions, or else two outright forward transactions for a given amount of the base currency, with different maturity dates, going in opposite directions.

- CURRENCY FUTURES = Conceptually, a series of outright forwards, one covering each period from one day’s marking to market and cash settlement to the next.

- CURRENCY SWAP = An exchange of principal in two different currencies at the beginning of the contract (sometimes omitted) and a re-exchange of same amount at the end; plus an exchange of two streams of interest payments covering each interest payment period, which is conceptually a series of outright forwards, one covering each interest payment period.

- CURRENCY OPTION = A one-way bet on the forward rate, at a price (premium) reflecting the market’s forecast of the volatility of that rate. A synthetic forward position can be produced from a combination of options, and a package of options can be replicated by taking apart a forward.
In the discussion below, the focus is narrowed from the foreign exchange market as a whole to how a dealer institution operates within the market.

In the United States, each of the 93 institutions regarded as active dealers—the 82 commercial banks and 11 investment banks and other institutions surveyed by the Federal Reserve—is an important participant in the foreign exchange market. But there are major differences in the size, scope, and focus of their foreign exchange activities. Some are market makers; others are not. Some engage in a wide range of operations covering all areas of foreign exchange trading; others concentrate on particular niches or currencies. They vary in the extent and the nature of the trading they undertake for customers and for their own accounts.

The bulk of foreign exchange turnover is handled by a small number of the 93 active dealers. Ten institutions—about 11 percent of the total—account for 51 percent of foreign exchange turnover in the United States. In other countries, there is comparable concentration. In the U.K. market, the market share of the top ten institutions also was 50 percent.

The very largest dealers in the United States compete with each other, and there are major changes in rankings over time. Only six of the top ten firms in 1995 remained in the top 10 in 1998.

### 1. Trading Room Setup

In appearance, the trading rooms of many major dealer institutions are similar in many respects. All have rows of screens, computers, telephones, dedicated lines to customers and to brokers, electronic dealing and brokering systems, news services, analytic and informational sources, and other communications equipment. All have various traders specializing in individual currencies and cross-currencies, in spot, forwards, swaps, and options; their specialists in offshore deposit markets and various bond markets; and their marketing groups. There are funds managers and those responsible for proprietary transactions using the dealer’s own funds. All have their affiliated “back offices”—not necessarily located nearby—where separate staffs confirm transactions consummated by the traders and execute the financial payments and receipts associated with clearance and settlement. Increasingly, there are “mid-office” personnel, checking on the validity of valuations used by the traders and other matters of risk management.

The equipment and the technology are critical and expensive. For a bank with substantial trading activity, which can mean hundreds of individual traders and work stations to equip, a full renovation can cost many, many millions of dollars. And that equipment may not last long—with technology advancing rapidly, the state of...
how dealers conduct foreign exchange operations

A dealer bank or other institution is likely to be undertaking various kinds of foreign exchange trading—making markets, servicing customers, arranging proprietary transactions—and the emphasis on each will vary among institutions.

Market making is basic to foreign exchange trading in the OTC market. The willingness of market makers to quote both bids and offers for particular currencies, to take the opposite side to either buyers or sellers of the currency, facilitates trading and contributes to liquidity and price stability, and is considered important to the smooth and effective functioning of the market. An institution may choose to serve as a market maker purely because of the profits it believes it can earn on the spreads between buying and selling prices. But it may also see advantages in that the market-making function can broaden in an important way the range of banking services that the institution can offer to clients. In addition, it can give the market-

The basic objectives and policy with respect to foreign exchange trading are set by senior management. They must decide which services the foreign exchange trading function will provide and how it will provide those services—often as part of a worldwide operation—in light of the bank’s financial and human resources and its attitude toward risk. The senior management must determine, in short, the bank’s fundamental business strategy—which includes, among other things, the emphasis to be placed on customer relationships and service vis-a-vis the bank’s trading for its own account—and how that strategy will deal with changing market conditions and other factors.

The trading rooms are the trenches where the battle is joined, where each trader confronts the market, customers, competitors, and other players, and where each institution plays out its fundamental business strategy and sees it succeed or fail. A winning strategy and a sound battle plan are essential, and teamwork—with each trader being aware of the actions of others in the group and of developments in related markets—is of enormous importance to success.
making institution access to both market information and market liquidity that are valuable in its other activities.

Much of the activity in trading rooms is focused on marketing services and maintaining customer relationships. Customers may include treasurers of corporations and financial institutions; managers of investment funds, pension funds, and hedge funds, and high-net worth individuals. A major activity of dealer institutions is managing customer business, including giving advice, suggesting strategies and ideas, and helping to carry out transactions and approaches that a particular customer may wish to undertake.

Dealers also trade foreign exchange as part of the bank’s proprietary trading activities, where the firm’s own capital is put at risk on various strategies. Whereas market making is usually reacting or responding to other people’s requests for quotes, proprietary trading is proactive and involves taking an initiative. Market making tends to be short-term and high volume, with traders focusing on earning a small spread from each transaction (or at least from most transactions)—with position-taking limited mainly to the management of working balances and reflecting views on very short-term forces and rate movements. A proprietary trader, on the other hand, is looking for a larger profit margin—in percentage points rather than basis points—based on a directional view about a currency, volatility, an interest rate that is about to change, a trend, or a major policy move—in fact, any strategic view about an opportunity, a vulnerability, or a mispricing in a market rate. Some dealers institutions—banks and otherwise—put sizeable amounts of their own capital at risk for extended periods in proprietary trading, and devote considerable resources to acquiring the risk analysis systems and other equipment and personnel to assist in developing and implementing such strategies. Others are much more limited in their proprietary trading.

3. TRADING AMONG MAJOR DEALERS—DEALING DIRECTLY AND THROUGH BROKERS

Dealer institutions trade with each other in two basic ways—direct dealing and through the brokers market. The mechanics of the two approaches are quite different, and both have been changed by technological advances in recent years.

Mechanics of Direct Dealing
Each of the major market makers shows a running list of its main bid and offer rates—that is, the prices at which it will buy and sell the major currencies, spot and forward—and those rates are displayed to all market participants on their computer screens. The dealer shows his prices for the base currency expressed in amounts of the terms currency. Both dollar rates and cross-rates are shown. Although the screens are updated regularly throughout the day, the rates are only indicative—to get a firm price, a trader or customer must contact the bank directly. In very active markets, quotes displayed on the screen can fail to keep up with actual market quotes. Also, the rates on the screen are typically those available to the largest customers and major players in the interbank market for the substantial amounts that the interbank
How dealers conduct foreign exchange operations

A trader can contact a market maker to ask for a two-way quote for a particular currency. Until the mid-1980s, the contact was almost always by telephone—over dedicated lines connecting the major institutions with each other—or by telex. But electronic dealing systems are now commonly used—computers through which traders can communicate with each other, on a bilateral, or one-to-one basis, on screens, and make and record any deals that may be agreed upon. These electronic dealing systems now account for a very large portion of the direct dealing among dealers.

As an example of direct dealing, if trader Mike were asking market maker Hans to give quotes for buying and selling $10 million for Swiss francs, Mike could contact Hans by electronic dealing system or by telephone and ask rates on “spot dollar-swissie on ten dollars.”

Hans might respond that “dollar-swissie is 1.4585-90,” or maybe “85-90 on 5,” but more likely, just “85-90,” if it can be assumed that the “big figure” (that is, 1.45) is understood and taken for granted. In any case, it means that Hans is willing to buy $10 million at the rate of CHF 1.4585 per dollar, and sell $10 million at the rate of CHF 1.4590 per dollar. Hans will provide his quotes within a few seconds and Mike will respond within a few seconds. In a fast-moving market, unless he responds promptly—in a matter of seconds—the market maker cannot be held to the quote he has presented. Also, the market maker can change or withdraw his quote at any time, provided he says “change” or “off” before his quote has been accepted by the counterparty.

It can all happen very quickly. Several conversations can be handled simultaneously on the dealing systems, and it is possible to complete a number of deals within a few minutes. When he hears the quotes, Mike will either buy, sell, or pass—there is no negotiation of the rate between the two traders. If Mike wants to buy $10 million at the rate of CHF 1.4590 per dollar (i.e., accept Hans’ offer price), Mike will say “Mine” or “I buy” or some similar phrase. Hans will respond by saying something like “Done—I sell you ten dollars at 1.4590.” Mike might finish up with “Agreed—so long.”

Each trader then completes a “ticket” with the name and amount of the base currency, whether bought or sold, the name and city of the counterparty, the term currency name and amount, and other relevant information. The two tickets, formerly written on paper but now usually produced electronically, are promptly transmitted to the two “back offices” for confirmation and payment. For the two traders, it is one more deal completed, one of 200-300 each might complete that day. But each completed deal will affect the dealer’s own limits, his bank’s currency exposure, and perhaps his approach and quotes on the next deal.

The spread between the bid and offer price in this example is 5 basis points in CHF per dollar, or about three one-hundredths of one percent of the dollar value. The size of the spread will, other things being equal, tend to be comparable among currencies on a percentage basis, but larger in absolute numbers the lower the value of the currency unit—i.e., the spread in the dollar-lira rate will tend to be wider in absolute number (of lire) than the spread in dollar-swissie, since the dollar sells for a larger absolute number of lire than of Swiss francs. The width of the spread can also be affected by a large number of other factors—the amount of liquidity in the market, the size of the transaction, the number of players, the time of day, the volatility of market conditions, the trader’s own...
position in that currency, and so forth. In the United States, spreads tend to be narrowest in the New York morning–Europe afternoon period, when the biggest markets are open and activity is heaviest, and widest in the late New York afternoon, when European and most large Asian markets are closed.

Mechanics of Trading Through Brokers: Voice Brokers and Electronic Brokering Systems

The traditional role of a broker is to act as a go-between in foreign exchange deals, both within countries and across borders. Until the 1990s, all brokering in the OTC foreign exchange market was handled by what are now called live or voice brokers.

Communications with voice brokers are almost entirely via dedicated telephone lines between brokers and client banks. The broker’s activity in a particular currency is usually broadcast over open speakers in the client banks, so that everyone can hear the rates being quoted and the prices being agreed to, although not specific amounts or the names of the parties involved.

A live broker will maintain close contact with many banks, and keep well informed about the prices individual institutions will quote, as well as the depth of the market, the latest rates where business was done, and other matters. When a customer calls, the broker will give the best price available (highest bid if the customer wants to sell and lowest offer if he wants to buy) among the quotes on both sides that he or she has been given by a broad selection of other client banks.

In direct dealing, when a trader calls a market maker, the market maker quotes a two-way price and the trader accepts the bid or accepts the offer or passes. In the voice brokers market, the dealers have additional alternatives. Thus, with a broker, a market maker can make a quote for only one side of the market rather than for both sides. Also, a trader who is asking to see a quote may have the choice, not only to hit the bid or to take (or lift) the offer, but also to join either the bid or the offer in the brokers market, or to improve either the bid or the offer then being quoted in the brokers market.

At the time a trade is made through a broker, the trader does not know the name of the counterparty. Subsequently, credit limits are checked, and it may turn out that one dealer bank must refuse a counterparty name because of credit limitations. In that event, the broker will seek to arrange a name-switch—i.e., look for a mutually acceptable bank to act as intermediary between the two original counterparties. The broker should not act as principal.

Beginning in 1992, electronic brokerage systems (or automated order-matching systems) have been introduced into the OTC spot market and have gained a large share of some parts of that market. In these systems, trading is carried out through a network of linked computer terminals among the participating users. To use the system, a trader will key an order into his terminal, indicating the amount of a currency, the price, and an instruction to buy or sell. If the order can be filled from other orders outstanding, and it is the best price available in the system from counterparties acceptable to that trader’s institution, the deal will be made. A large order may be matched with several small orders.

If a new order cannot be matched with outstanding orders, the new order will be entered into the system, and participants in the system from other banks will have access to it. Another player may accept the order by pressing a “buy” or “sell” button and a transmit button. There are other buttons to press for withdrawing orders and other actions.
Electronic brokering systems now handle a substantial share of trading activity. These systems are especially widely used for small transactions (less than $10 million) in the spot market for the most widely traded currency pairs—but they are used increasingly for larger transactions and in markets other than spot. The introduction of these systems has resulted in greater price transparency and increased efficiency for an important segment of the market. Quotes on these smaller transactions are fed continuously through the electronic brokering systems and are available to all participating institutions, large and small, which tends to keep broadcast spreads of major market makers very tight. At the same time electronic brokering can reduce incentives for dealers to provide two-way liquidity for other market participants. With traders using quotes from electronic brokers as the basis for prices to customers and other dealers, there may be less propensity to act as market maker. Large market makers report that they have reduced levels of first-line liquidity. If they need to execute a trade in a single sizeable amount, there may be fewer reciprocal counterparties to call on. Thus, market liquidity may be affected in various ways by electronic brokering.

Proponents of electronic brokering also claim there are benefits from the certainty and clarity of trade execution. For one thing there are clear audit trails, providing back offices with information enabling them to act quickly to reconcile trades or settle differences. Secondly, the electronic systems will match orders only between counterparties that have available credit lines with each other. This avoids the problem sometimes faced by voice brokers when a dealer cannot accept a counterparty he has been matched with, in which case the voice broker will need to arrange a “credit switch,” and wash the credit risk by finding an acceptable institution to act as intermediary. Further, there is greater certainty about the posted price and greater certainty that it can be traded on. Disputes can arise between voice brokers and traders when, for example, several dealers call in simultaneously to hit a given quote. These uncertainties are removed in an electronic process. But electronic broking does not eliminate all conflicts between banks. For example, since dealers typically type into the machine the last two decimal points (pips) of a currency quote, unless they pay close attention to the full display of the quote, they may be caught unaware when the “big figure” of a currency price has changed.

With the growth of electronic broking, voice brokers and other intermediaries have responded to the competitive pressures. Voice brokers have emphasized newer products and improved technology. London brokers have introduced a new automated confirmation system, designed to bring quick confirmations and sound audit trails. Others have emphasized newer products and improved technology. There have also been moves to focus on newer markets and market segments.

The two basic channels, direct dealing and brokers—either voice brokers or electronic brokering systems—are complementary techniques, and dealers use them in tandem. A trader will use the method that seems better in the circumstances, and will take advantage of any opportunities that an approach may present at any particular time. The decision on whether to pay a fee and engage a broker will depend on a variety of factors related to the size of the order, the currency being traded, the condition of the market, the time available for the trade, whether the trader wishes to be seen in the market (through direct dealing) or wants to operate more discreetly (through brokers), and other considerations.
Typically the foreign exchange department of a bank will meet each morning, before trading starts, review overnight developments, receive reports from branches and affiliated outlets in markets that opened earlier, check outstanding orders from customers, discuss their views toward the market and the various currencies, and plan their approaches for the day. As market events unfold, they may have to adapt their view and modify their approach, and the decisions on whether, when, and how to do so can make the difference between success and failure.

Each institution has its own decision-making structure based on its own needs and resources. A chief dealer supervises the activities of individual traders and has primary responsibility for hiring and training new personnel. The chief dealer typically reports to a senior officer responsible for the bank’s international asset and liability area, which includes, not only foreign exchange trading, but also Eurodollar and other offshore deposit markets, as well as derivatives activities intimately tied to foreign exchange trading. Reporting to the chief dealer are a number of traders specializing in one or more currencies. The most actively traded currencies are handled by the more senior traders, often assisted by a junior person who may also handle a less actively traded currency. But the actions of any trader, regardless of rank, commit the bank’s funds. All need to be on their toes. Even a day trader whose objective may be simply to buy at his bid price and sell at his offer is in a better position to succeed if he is well informed, and can read the market well, see where rates may be headed, and understand the forces at play. He must have a clear understanding of his currency position, his day’s net profit or loss, and whether and by how much to shade his quotes in one direction or the other.

Many senior traders have broad responsibility for the currencies they trade—quoting prices to customers and other dealers, dealing directly and with the brokers market, balancing daily payments and receipts by arranging swaps and other transactions, and informing and advising customers. They may have certain authority to take a view on short-term exchange rate and interest rate movements, resulting in a short or long position within authorized limits. The chief dealer is ultimately responsible for the profit or loss of the operation, and for ensuring that management limits to control risk are fully observed.

Most large market-making institutions have “customer dealers” or “marketers” in direct contact with corporations and other clients, advising customers on strategy and carrying out their instructions. This allows individual traders in spot, forwards, and other instruments to concentrate on making prices and managing positions. If the client deals, the marketer must make sure that all of the various traders involved in the transactions are informed of the particulars.

The 1998 Federal Reserve turnover survey indicated that brokers handled 41 percent of spot transactions, and a substantially smaller percentage of outright forwards and FX swaps. Altogether, 24 percent of total U.S. foreign exchange activity in the three traditional markets was handled by brokers. In the brokers market, 57 percent of turnover is now conducted through automated order-matching systems, or electronic brokering, compared with 18 percent in 1995.
When a customer asks a market-making institution for the rates at which it is willing to buy and sell a particular currency, the response will be based on a number of factors. In deciding what bid and offer prices to quote, the trader takes into account the current quotations in the market, the rates at which the brokers are transacting business, the latest trends and expectations, whether the bank is long or short the currency in question, and views about where rates are headed. The trader is expected to be knowledgeable about both “fundamental” analysis (broad macroeconomic and financial trends underlying the supply and demand conditions for currencies that are being traded) and “technical” analysis (charts showing price patterns and volume trends). The trader also should be aware of the latest economic news, political developments, predictions of experts, and the technical position of the various currencies in the market. In bid and offer price quotes, the trader also may be influenced by the size of the trade—on the one hand, a small trade may call for a less favorable rate to cover fixed costs; on the other hand, a large trade may be much more difficult to offset.

When making quotes on outright forwards and FX swaps, in addition to understanding all the factors that may be influencing the spot rate, the trader must know the interbank swap rates for the currency in question—since the swap rate will reflect the interest rate differential between the two currencies being traded, and is the critical factor in determining the amount of premium or discount at which the forward exchange rate will trade. The trader, in addition, must be aware of the maturity structure of the contracts already outstanding in his bank’s foreign exchange book, and whether the proposed new transaction would add to or reduce the mismatches. Of course, in offering a quote for an option, a trader must consider other complex factors. The trader will have loaded into his computer various formulas for estimating the future volatility of the currency involved, along with spot and forward exchange rates and interest rates, so that he can very quickly calculate and quote the price of the premium when given the particulars of the transaction.

On top of all this, in setting quotes, a trader will take into account the relationship between the customer or counterparty and his institution. If it is a valued customer, the trader will want to consider the longer-term relationship with that customer and its importance to the longer-term profitability of the bank. Similarly, when dealing with another market maker institution, the trader will bear in mind the necessity of being competitive and also the benefit of relationships based on reciprocity.

When asked for a quote, the trader must respond immediately, making an instantaneous assessment of these thousand and one factors. Quotes have to be fine enough to attract customers and to win an appropriate share of the business—but also not too fine, since the trader wants to avoid excessive or inappropriate risk and to make profits. A trader wants to be an active participant in the market—it’s helpful in keeping abreast of what’s going on, and he wants others to think of him as a potential counterparty—but he doesn’t want to “over-trade” or feel he must be in on every trade.

As the traders in a foreign exchange department buy and sell various currencies throughout the day in spot, forward, and FX swap transactions, the trading book or foreign exchange position of the institution changes, and long and short positions in individual currencies arise. Since every transaction involves an exchange of one currency for another, it results in
Every time a deal to buy or sell foreign exchange is agreed upon by two traders in their trading rooms, a procedure is set in motion by which the “back offices” of the two institutions confirm the transaction and make the necessary funds transfers. The back office is usually separated physically from the trading room for reasons of internal control—but it can be next door or thousands of miles away.

For each transaction, the back office receives for processing the critical information with respect to the contract transmitted by the traders, the brokers, and the electronic systems. The back offices confirm with each other the deals agreed upon and the stated terms—a procedure that can be done by telephone, fax, or telex, but that is increasingly handled electronically by systems designed for this purpose. If there is a disagreement between the two banks on a relevant factor, there will be discussions to try to reach an understanding. Banks and other institutions regularly tape record all telephone conversations of traders. Also, electronic dealing systems and electronic broking systems automatically record their communications. These practices have greatly reduced the number of disputes over what has been agreed to by the two traders. In many cases, banks participate in various bilateral and multilateral netting arrangements with each other, instead of settling on the basis of each individual transaction. As discussed in Chapter 8, netting, by reducing the amounts of gross payments, can be both a cheaper and safer way of settling.

5. BACK OFFICE PAYMENTS AND SETTLEMENTS

Every time a deal to buy or sell foreign exchange is agreed upon by two traders in their trading rooms, a procedure is set in motion by which the “back offices” of the two institutions confirm the transaction and make the necessary funds transfers. The back office is usually separated physically from the trading room for reasons of internal control—but it can be next door or thousands of miles away.

For each transaction, the back office receives for processing the critical information with respect to the contract transmitted by the traders, the brokers, and the electronic systems. The back offices confirm with each other the deals agreed upon and the stated terms—a procedure that can be done by telephone, fax, or telex, but that is increasingly handled electronically by systems designed for this purpose. If there is a disagreement between the two banks on a relevant factor, there will be discussions to try to reach an understanding. Banks and other institutions regularly tape record all telephone conversations of traders. Also, electronic dealing systems and electronic broking systems automatically record their communications. These practices have greatly reduced the number of disputes over what has been agreed to by the two traders. In many cases, banks participate in various bilateral and multilateral netting arrangements with each other, instead of settling on the basis of each individual transaction. As discussed in Chapter 8, netting, by reducing the amounts of gross payments, can be both a cheaper and safer way of settling.
Payments instructions are promptly exchanged—in good time before settlement—indicating, for example, on a dollar-yen deal, the bank and account where the dollars are to be paid and the bank and account where the yen are to be paid. On the value date, the two banks or correspondent banks debit-credit the clearing accounts in response to the instructions received. Since 1977, an automated system known as SWIFT (Society for the Worldwide Interbank Financial Telecommunications) has been used by thousands of banks for transferring payment instructions written in a standardized format among banks with a significant foreign exchange business.

When the settlement date arrives, the yen balance is paid (for an individual transaction or as part of a larger netted transaction) into the designated account at a bank in Japan, and a settlement occurs there. On the U.S. side, the dollars are paid into the designated account at a bank in the United States, and the dollar settlement—or shift of dollars from one bank account to another—is made usually through CHIPS (Clearing House Interbank Payments System), the electronic payments system linking participating depository institutions in New York City.

After the settlements have been executed, the back offices confirm that payment has indeed been made. The process is completed. The individual, or institution, who wanted to sell dollars for yen has seen his dollar bank account decline and his bank account in yen increase; the other individual, or institution, who wanted to buy dollars for yen has seen his yen bank deposit decline and his dollar bank account increase.
Market risk, in simplest terms, is price risk, or “exposure to (adverse) price change.” For a dealer in foreign exchange, two major elements of market risk are exchange rate risk and interest rate risk—that is, risks of adverse change in a currency rate or in an interest rate.

Exchange rate risk is inherent in foreign exchange trading. A trader in the normal course of business—as he buys or sells foreign currency to a customer or to another bank—is creating an “open” or “uncovered” position (long or short) for his bank in that currency, unless he is covering or transferring out of some previous position. Every time a dealer takes a new foreign exchange position—in spot, outright forwards, currency futures, or currency options—that position is immediately exposed to the risk that the exchange rate may move against it, and the dealer remains exposed until the transaction is hedged or covered by an offsetting transaction. The risk is continuous—and a gap of a few moments or less can be long enough to see what was thought to be a profitable transaction changed to a costly loss.

Interest rate risk arises when there is any mismatching or gap in the maturity structure. Thus, an uncovered outright forward position can change in value, not only because of a change in the spot rate (foreign exchange risk), but also because of a change in interest rates (interest rate risk), since a forward rate reflects the interest rate differential between the two currencies. In an FX swap, there is no shift in foreign exchange exposure, and the market risk is interest rate risk. In addition to FX swaps and currency swaps, outright forwards, currency futures, and currency options are all subject to interest rate risk.
There are two forms of market risk—an adverse change in absolute prices, and an adverse change in relative prices. With respect to relative price changes, “basis risk” is the possibility of loss from using, for example, a U.S. dollar position to offset Argentine currency exposure (in the expectation that the Argentine currency will move in step with the U.S. dollars), and then seeing the Argentine currency fail to maintain the relationship with the U.S. dollar that had been expected. It can also occur if a short-term interest rate that was used to offset a longer-term interest rate exposure fails to maintain the expected relationship because of a shift in the yield curve. To limit basis risk, traders try to stay well informed of statistical correlations and co-variances among currencies, as well as likely yield curve trends.

**Measuring and Managing Market Risk**

Various mechanisms are used to control market risk, and each institution will have its own system. At the most basic trading room level, banks have long maintained clearly established volume or position limits on the maximum open position that each trader or group can carry overnight, with separate—probably less restrictive—intraday or “daylight” limits on the maximum open position that can be taken during the course of a trading session. These limits are carefully and closely monitored, and authority to exceed them, even temporarily, requires approval of a senior officer.

But volume limits alone are not enough. A $10 million open position in a very volatile currency represents a much bigger risk to profits than $10 million exposure in a relatively stable currency. Banks and other firms dealing in foreign exchange put limits, not only on the overall volume of their foreign exchange position, but also on their estimated potential losses during, say, the next 24 hours, which they estimate through calculations of “value at risk” (VAR), “daily earnings at risk” (DEAR), or other dollars-at-risk measurements. Thus, a trading unit might have an overnight volume limit of say, $10 million, and also a VAR limit of, say, $150,000.

**Value at Risk**

The rapid growth of derivatives in recent years—growth both in the amounts traded and in the innovative new products developed—has introduced major new complexities into the problem of measuring market risk. Banks and other institutions have seen the need for new and more sophisticated techniques adapted to the changed market situation.

Consider, for example, the question of the valuation of derivatives. If a trader entered into a contract for the forward purchase of $10 million of pounds sterling six months hence at today’s 6-month forward price for GBP, the notional or face value of the contract would be $10 million. The market value (gross replacement value) of the contract would at the outset be zero—but that market value could change very abruptly and by significant amounts. Neither the notional value of that forward contract nor the snapshot of the market value as of a particular moment provides a very precise and comprehensive reflection of the risk, or potential loss, to the trader’s book. For currency options, the problem is much more complex—the value of an option is determined by a number of different elements of market risk, and values can change quickly, moving in a non-linear fashion. Market participants need a more dynamic way of assessing market risk as it evolves over time, rather than measuring risk on the basis of a snapshot as of one particular moment, or by looking at the notional amounts of funds involved.
In a report of the Group of Thirty entitled *Derivatives: Practices and Principles*, industry members recommended a series of actions to assist in the measurement of market risk. They recommended that institutions adopt a “value at risk” (VAR) measure of market risk, a technique that can be applied to foreign exchange and to other products. It is used to assess not only the market risk of the foreign exchange position of the trading room, but also the broader market risk inherent in the foreign exchange position resulting from the totality of the bank or firm’s activities.

VAR estimates the potential loss from market risk across an entire portfolio, using probability concepts. It seeks to identify the fundamental risks that the portfolio contains, so that the portfolio can be decomposed into underlying risk factors that can be quantified and managed. Employing standard statistical techniques widely used in other fields, and based in part on past experience, VAR can be used to estimate the *daily statistical variance*, or standard deviation, or volatility, of the entire portfolio. On the basis of that estimate of variance, it is possible to estimate the expected loss from adverse price movements with a specified probability over a particular period of time (usually a day).

Thus, a bank might want to calculate the maximum estimated loss in its foreign exchange portfolio in one day from market risk on the basis of, say, a 97.5 confidence interval. It could then calculate that on 39 days out of 40 days, the expected loss from market risk (adverse price changes) would be no greater than “x.”

VAR is regarded by market participants as helpful to an institution in assessing its market risk and providing a more comprehensive picture than is otherwise available. The institution can use the calculations as a framework for considering other questions—e.g., what steps, if any, should be taken to hedge or adjust the book, how does the situation look in terms of the institution’s strategy and tolerance for risk, and other management issues.

However, VAR has limitations. It provides an *estimate*, not a *measurement*, of potential loss. It does not predict by *how much* the loss will exceed that amount in the one day in forty (or other selected probability) when the estimated loss will exceed the specified amount of VAR. The calculations are based on historical experience and other forecasts of volatility, and are valid only to the extent that the assumptions are valid. In using past experience, there are always questions of whether the past will be prologue, which period of past experience is most relevant, and how it should be used. Many alternative approaches are possible: Should the formula be weighted toward the recent past? Should a more extensive period of history be covered? Should judgments about the fundamental condition of the market be introduced?

Also, there are certain statistical limitations. VAR calculations use standard deviation measurements—the familiar bell-shaped curve, which reflects a “normal” distribution. But there is empirical evidence that daily exchange rate changes usually do not closely fit a normal distribution; they exhibit a property called “leptokurtosis,” which means they have “fatter tails” (more outliers) and a higher mid-range than is seen in a normal distribution. Some practitioners make adjustments (e.g., they look toward a 97.5%, or 99%, rather than a 95%, confidence level) in light of these uncertainties.
Credit risk, inherent in all banking activities, arises from the possibility that the counterparty to a contract cannot or will not make the agreed payment at maturity. When an institution provides credit, whatever the form, it expects to be repaid. When a bank or other dealing institution enters a foreign exchange contract, it faces a risk that the counterparty will not perform according to the provisions of the contract. Between the time of the deal and the time of the settlement, be it a matter of hours, days, or months, there is an extension of credit by both parties and an acceptance of credit risk by the banks or other financial institutions involved. As in the case of market risk, credit risk is one of the fundamental risks to be monitored and controlled in foreign exchange trading.

Indeed, in calculating risk-based capital requirements, the bank supervisors of the G-10 major industrial nations, acting through the Basle Committee on Bank Supervision, now allow large banking institutions with major trading activities in foreign exchange and other instruments to measure their market risk through their internal value-at-risk models. Thus, each institution can use its own internal model as the framework for making its calculations of its market risk-based capital requirement—but subject to the approval of the appropriate supervisor, and to conformity with certain minimum qualitative and quantitative standards regarding measurement and management of market risk.

Credit risk, inherent in all banking activities, arises from the possibility that the counterparty to a contract cannot or will not make the agreed payment at maturity. When an institution provides credit, whatever the form, it expects to be repaid. When a bank or other dealing institution enters a foreign exchange contract, it faces a risk that the counterparty will not perform according to the provisions of the contract. Between the time of the deal and the time of the settlement, be it a matter of hours, days, or months, there is an extension of credit by both parties and an acceptance of credit risk by the banks or other financial institutions involved. As in the case of market risk, credit risk is one of the fundamental risks to be monitored and controlled in foreign exchange trading.

In banking, the reasons a counterparty may be unwilling or unable to fulfill its contractual obligations are manifold. There are cases when a corporate customer enters bankruptcy, or a bank counterparty becomes insolvent, or foreign exchange or other controls imposed by governmental authorities prohibit payment.

If a counterparty fails before the trade falls due for settlement (pre-settlement risk), the bank’s position is unbalanced and the bank is exposed to loss for any changes in the exchange rate that have occurred since the contract was originated. To restore its position, the bank will need to arrange a new transaction, and very likely at an adverse exchange rate, since no one defaults on a contract that yields positive gains. In situations of bankruptcy, a trustee for the bankrupt company will endeavor to “cherry pick,” or perform according to the terms on those contracts that are advantageous to the bankrupt party, while disclaiming those that are disadvantageous.

In foreign exchange trading, banks have long been accustomed to dealing with the broad and pervasive problem of credit risk. “Know your customer” is a cardinal rule and credit limits or dealing limits are set for each counterparty—presumably after careful study of the
counterparty’s creditworthiness—and adjusted in response to changes in financial circumstances. Over the past decade or so, banks have become willing to consider “margin trading” when a client requires a dealing limit larger than the bank is prepared to provide. Under this arrangement, the client places a certain amount of collateral with the bank and can then trade much larger amounts. This practice often is used with leveraged and hedge funds. Also, most institutions place separate limits on the value of contracts that mature in a single day with a single customer, and some restrict dealings with certain customers to spot only, unless there are compensating balances. A bank’s procedures for evaluating credit risk and controlling exposure are reviewed by bank supervisory authorities as part of the regular examination process.

**Settlement Risk—A Form of Credit Risk**

It was noted in Chapter 2 that foreign exchange trading is subject to a particular form of credit risk known as settlement risk or Herstatt risk, which stems in part from the fact that the two legs of a foreign exchange transaction are often settled in two different time zones, with different business hours. Also noted was the fact that market participants and central banks have undertaken considerable initiatives in recent years to reduce Herstatt risk. Two such efforts are worth mentioning.

In October 1994, the New York Foreign Exchange Committee, a private-sector group sponsored by the Federal Reserve Bank of New York, published a study entitled *Reducing Foreign Exchange Settlement Risk*, which examined the problem of settlement risk from a broad perspective. The Committee found that foreign exchange settlement risk is much greater than previously recognized and lasts longer than just the time zone differences in different markets. In the worst case, a firm can be “at risk” for as long as 72 hours between the time it issues an irrevocable payment instruction on one leg of the transaction and the time payment is received irrevocably and unconditionally on the other leg. The Committee recommended a series of private sector “best practices” to help reduce Herstatt risk, including establishing arrangements to net payments obligations, setting prudent exposure limits, and reducing the time taken for reconciliation procedures.

More recently, in March 1996, the central banks of the major industrial nations issued a report through the Bank for International Settlements, called *Settlement Risk in Foreign Exchange Transactions*, which highlighted the pervasive dimensions of settlement risk, expressed concern about the problem, and suggested an approach for dealing with it. The report confirmed the finding of the New York Foreign Exchange Committee that foreign exchange settlement exposure can last up to several days, and it recommended a three-track strategy calling for:

- individual banks to improve management and control of their foreign exchange settlement exposures;
- industry groups in the private sector to provide services that will contribute to the risk reduction efforts of individual banks; and
- central banks to improve national payment systems and otherwise stimulate appropriate private sector actions.

Some steps have been taken to reduce settlement risk, and others are being considered to help deal with this problem. There are “back-end” solutions, using netting and exchange clearing arrangements to modify the settlement process,
ARRANGEMENTS FOR DEALING WITH SETTLEMENT RISK

One of the aims of netting is to reduce settlement risk by providing for an agreed offsetting of positions or obligations by trading partners. Netting can take either a *bilateral* or a *multilateral* form. *Bilateral* netting is designed to reduce counterparty exposure by automatically offsetting concurrent obligations of each of two parties to the other. *Multilateral* netting extends this practice to more than two participants—calculating each participant's “net-net” position, or position against the group of participants as a whole and settling through a central party. In recent years, a number of procedural and legal changes have been introduced in various countries to facilitate netting arrangements.

*Bilateral* netting arrangements for foreign exchange were introduced a number of years ago, through facilities in FXNET, SWIFT, and VALUENET.

More comprehensive, *multilateral* netting schemes were subsequently introduced, operating through *ECHO* (or exchange clearing house) and *Multinet*. The two competing systems subsequently merged.

Some of the new “front-end” approaches—all of which are in various stages of study and development—reflect the fact that *cash delivery* of the various currencies is needed by the participants in only a small percentage of foreign exchange transactions.

One novel “front-end” approach designed to reduce settlement risk from foreign exchange trades beyond conventional bilateral netting systems is called “netting +.” Under this technique, each day (say, day 1) two “netting +” counterparties scheduled to settle a dollar amount for a non-dollar amount “tomorrow” (day 2) will, instead, arrange a “tom-next” (or tomorrow/next day) swap for the non-dollar amount and the dollar equivalent, effectively rolling forward the settlement one day (to day 3) and combining it with other settlements scheduled for that day. The only payment (on day 2) is a (usually relatively small) dollar amount to cover any difference between the contracted price and that day’s market price. This approach is in the developmental stage.

Another experimental “front-end” approach is “foreign exchange difference settled” (FXDS), under which the two counterparties, instead of exchanging two full payments at settlement, agree to settle only the net amount by which the relevant values of the two currencies have changed.

A group of leading international institutions called the “Group of 20” has proposed a concept of “continuous linked settlement” (CLS) for reducing settlement risk, in which a specialized bank would act as clearing institution, providing for “real time” settlement—payment versus payment, or “PVP,” in major currencies among participating institutions. The participants expect the system to begin operating in the year 2000.
Numerous other forms of risk can be involved in foreign exchange trading, just as in other financial activities.

Steps have also been taken to improve central bank services in order to reduce foreign exchange settlement risk. At the beginning of 1998, the Federal Reserve extended Fedwire operating hours. Fedwire is now open 18 hours a day. Its operational hours overlap with the national payment systems in all other major financial centers around the world. Similarly, CHIPS has expanded its hours and introduced other improvements.

**Sovereign Risk—A Form of Credit Risk**
Another element of credit risk of importance in foreign exchange trading is sovereign risk—that is, the political, legal, and other risks associated with a cross-border payment. At one time or another, many governments have interfered with international transactions in their currencies. Although in today’s liberalized markets and less regulated environment there are fewer and fewer restrictions imposed on international payments, the possibility that a country may prohibit a transfer cannot be ignored—the United States Government has imposed such restrictions on various occasions. In order to limit their exposure to this risk, banks and other foreign exchange market participants sometimes establish ceilings for individual countries, monitor regulatory changes, watch credit ratings, and, where practicable, obtain export risk guaranties and other forms of insurance.

**Group of Thirty Views on Credit Risk**
As with market risk, the management of credit risk has become more complicated and more sophisticated with the development of derivative instruments and, more generally, the evolution of financial markets. The Group of Thirty report, Derivatives: Practices and Principles, addressed questions of measuring, monitoring, and managing credit risk in derivatives activity. The report recommended that each dealer and end-user of derivatives should assess the credit risk arising from derivatives activities based on frequent measures of current and potential exposure against credit limits. It further recommended that dealers and end-users use one master agreement as widely as possible, and that each counterparty document existing and future derivatives transactions, including foreign exchange forwards and options, and cover various types of “netting” arrangements. The report also recommended that regulators and supervisors recognize the benefits of netting arrangements and encourage their wider use.

More recently, other ideas have been put forward for a portfolio approach to credit risk, similar to the value-at-risk approach to market risk. The aim would be to produce a single number for how much a bank stands to lose on a portfolio of credits of varying characteristics, and thus to determine how much the bank should hold in reserve against that portfolio.

### 3. Other Risks

Numerous other forms of risk can be involved in foreign exchange trading, just as in other financial activities.
the course of a day, or, in extreme cases, within minutes—and a bank may find itself unable to liquidate assets quickly without loss or to manage unplanned decreases or changes in funding sources. Given the size, breadth, and depth of the foreign exchange market, liquidity risk is less a danger than in most financial markets.

There are legal risks, or the risk of loss that a contract cannot be enforced, which may occur, for example, because the counterparty is not legally capable of making the binding agreement, or because of insufficient documentation or a contract in conflict with statutes or regulatory policy. While such legal risks are encountered in traditional banking, they have taken new forms with the growth in derivatives, since many existing laws and regulations were written before these products and transactions came into being, and it is not clear how the laws and regulations apply.

Also, foreign exchange trading and other financial businesses face considerable operational risks—that is, the risk of losses from inadequate systems, human error, or a lack of proper oversight policies and procedures and management control. There are numerous examples of problems and failures in financial institutions around the world related to inadequate systems and controls—although employee dishonesty of one sort or another is very often involved.

All of these risks develop, evolve, and mutate as conditions change and new foreign exchange techniques and instruments are created. In foreign exchange trading, as in other banking and financial transactions, the matter of managing risk is a continuous and exacting part of doing business.
During the first decade and a half after World War II, the United States monetary authorities did not actively intervene or directly operate in the foreign exchange market for the purpose of influencing the dollar exchange rate or exchange market conditions. Under the Bretton Woods par value exchange rate system, the obligation of the United States was to assure the gold convertibility of the dollar at $35 per ounce to the central banks and monetary authorities of IMF members. The actions of other governments, intervening in dollars as appropriate to keep their own currencies within the one percent of dollar par value that IMF rules required, maintained the day-to-day market level of the dollar within those narrow margins. Under that arrangement, the United States played only a passive role in the determination of exchange rates in the market: In a system of “n” currencies, not every one of the “n” countries can independently set its own exchange rate against the others. Such a system would be over-determined. At least one currency must be passive, and the dollar served as that “nth” currency.

In the early 1960s, the United States became more active in exchange market operations. By then, the United States had begun to experience its own serious and prolonged balance of payments problems. Increasingly, the United States became concerned about protecting its gold stock and maintaining the credibility of the dollar's link to gold and the official gold price of $35 per ounce on which the world par value system of exchange rates was based.

The Bretton Woods fixed exchange rate system became unsustainable over time—it broke down in 1971 and finally collapsed in 1973. In 1978, after much of the world had moved de facto to a floating exchange rate system, the IMF Articles were amended to change the basic obligation of IMF members. No longer were members obliged to maintain par values; instead, they were “to collaborate with the Fund and other members to assure orderly exchange arrangements and to promote a stable system of exchange rates.” Each member was authorized to adopt the exchange arrangement of its choice—fixed or floating, tied to another currency or to a basket of currencies—subject,
During the Bretton Woods years, although there were a number of changes in various nations’ par values, exchange rate fluctuations were relatively modest most of the time. However, exchange market pressures showed in other ways. Much attention was paid to the size of U.S. gold reserves in relation to the size of U.S. official dollar liabilities—the dollar balances held by official institutions in other countries. Various measures were taken to protect the U.S. gold stock and the credibility of dollar convertibility for foreign official holders. Many actions were taken by the U.S. authorities to hold down the growth of what foreign central banks might regard as their “excess” dollar balances, with a view to reducing the pressure for conversion of official dollar holdings into gold. Specific U.S. actions taken during the Bretton Woods par value period included:

- borrowing foreign currencies from foreign monetary authorities through reciprocal credit lines (swap lines) for the purpose of selectively buying dollars from certain foreign central banks that might otherwise have sought to convert those dollars into gold;
- selling foreign-currency-denominated bonds (called Roosa bonds after the then Under-Secretary of the Treasury) to mop up excess dollars that might otherwise be converted by foreign central banks into gold;
- acquiring foreign currencies by drawing down the U.S. reserve position at the IMF, again using those currencies to buy excess dollars from other central banks and also to pay off swap debts;
- cooperating with monetary authorities of other major countries to buy and sell gold in the free market to maintain the free market dollar price of gold close to the official price of $35 per ounce; and
- intervening, on occasion, directly in the foreign exchange market during the 1960s and early 1970s in order to reduce the pressures to convert dollars into gold, and to maintain or restore orderly conditions in volatile currency markets.

Currently, the exchange rate regime of the United States is recorded by the IMF under the classification of “Independent Floating,” with the notation that the exchange rate of the dollar is determined freely in the foreign exchange market. Of course, the United States does on occasion intervene in the foreign exchange market, as described below. However, in recent periods such occasions have been rare; the United States has intervened only when there was a clear and convincing case that intervention was called for.
The Foreign Exchange Market in the United States

The foreign exchange market activities of the U.S. Treasury and the Federal Reserve

**AUTHORIZATION AND MANAGEMENT OF INTERVENTION OPERATIONS**

By law and custom, the Secretary of the Treasury is primarily and directly responsible to the President and the Congress for formulating and defending U.S. domestic and international economic policy, assessing the position of the United States in the world economy, and conducting international negotiations on these matters. At the same time, foreign exchange markets are closely linked to money markets and to questions of monetary policy that are within the purview of the Federal Reserve. There is a distinct role and responsibility for the Federal Reserve, working with the Treasury and in cooperation with foreign central banks that operate in their own markets. For many years, the Treasury and the Federal Reserve have recognized the need to cooperate in the formulation and implementation of exchange rate policy.

The Treasury and the Federal Reserve each have independent legal authority to intervene in the foreign exchange market. Since 1978, the financing of U.S. exchange market operations has generally been shared between the two. Intervention by the Treasury is authorized by the Gold Reserve Act of 1934 and the Bretton Woods Agreements Act of 1944. Intervention by the Federal Reserve System is authorized by the Federal Reserve Act. It is clear that the Treasury cannot commit Federal Reserve funds to intervention operations. It also is clear that any foreign exchange operations of the Federal Reserve will be conducted, in the words of the Federal Open Market Committee (FOMC), “in close and continuous cooperation with the United States Treasury.” In practice, any differences between the Treasury and the Federal Reserve on these matters have generally been worked out satisfactorily. Cooperation is facilitated by the fact that all U.S. foreign exchange market operations are conducted by the Foreign Exchange Desk of the Federal Reserve Bank of New York, acting as agent for both the Treasury and the Federal Reserve System.

The Treasury's foreign exchange operations are financed through the Exchange Stabilization Fund (ESF) of the Treasury. The ESF was created in the early 1930s, utilizing profits resulting from the increase in the official dollar price of gold enacted at that time. The ESF is available to the Secretary of the Treasury, with the approval of the President, for trading in gold and foreign exchange.

The Federal Reserve's foreign exchange operations are financed through a System account in which all 12 Federal Reserve Banks participate. The System account operates under the guidance of the FOMC, the System's principal policy-making body. Transactions are executed by the Federal Reserve Bank of New York, under the direction of the Manager of the System Open Market Account, who is responsible for operations of both the Domestic Desk and the Foreign Exchange Desk.

Three formal documents of the FOMC provide direction and oversight for the System's foreign exchange operations and set forth guidance for the Federal Reserve Bank of New York in conducting these operations. The three documents, which are subject to annual FOMC approval and amended as appropriate, are (1) the **Authorization** for Foreign Currency Operations, (2) the **Foreign Currency Directive**, and (3) the **Procedural Instructions**. They provide the framework within which the Foreign Exchange Desk of the Federal Reserve Bank of New York conducts foreign exchange operations for the

(continued on page 88)
Since the authorization of floating in the 1978 amendment of the IMF articles, U.S. intervention operations generally have been carried out under the broad rubric of “countering disorderly market conditions.” However, that general objective has been interpreted in quite different ways at different times.

The Foreign Exchange Desk consults and obtains clearance from the FOMC, its Foreign Currency Subcommittee, or the Federal Reserve Chairman for any operations of a certain type or magnitude between FOMC meetings. In addition to establishing the framework for Federal Reserve System foreign currency operations through these formal documents, the FOMC receives at each of its scheduled meetings a report by the Manager of the System Open Market Account of any U.S. intervention operations that have taken place since the previous meeting, and the circumstances of the operations. Formal FOMC approval is required of all operations financed through the System account.

The FOMC also is responsible for any authorization of warehousing foreign currencies for the Treasury and Exchange Stabilization Fund. Warehousing is a mechanism whereby the Federal Reserve can—at its sole discretion—enter into temporary swap transactions with the Exchange Stabilization Fund of the Treasury, providing dollars in exchange for an equivalent amount of foreign currency, with an agreement to reverse the payments at a specified exchange rate at a specified future date. Thus, the warehousing facility can temporarily supplement the U.S. dollar resources of the Treasury and the ESF for financing their purchases of foreign currencies and related international operations against deposits of foreign currencies. All exchange rate risk is borne by the Treasury. Warehousing transactions have been undertaken on many occasions over a long period of years.
times over that period, and the approach to exchange market intervention has varied with the interpretation. During some periods, “countering disorderly market conditions” has been interpreted very narrowly, and intervention has been limited to rare and extreme situations; during other periods, it has been interpreted broadly and operations have been extensive.

During the first dozen years after exchange rate floating was sanctioned by 1978 IMF amendment, the United States changed its approach and its goals several times. There were a number of key turning points, and the U.S. experience from 1978 to 1990 breaks down into five distinct periods.

The first period covered the years after the amendment of the IMF articles in 1978 until early 1981. During 1978, the dollar was under heavy downward market pressure and the exchange rate declined sharply, at a time of rising international oil prices, high U.S. inflation, and a deteriorating balance of payments. In November 1978, a major new dollar support program was introduced, based on the conclusion that “the dollar’s decline had gone beyond what could be justified by underlying conditions,” and the U.S. authorities announced that a major effort would be undertaken to reverse the dollar’s decline. The program provided for raising a large war chest of up to $30 billion equivalent in foreign currencies—by Treasury borrowing of foreign currencies in overseas capital markets, U.S. drawings from its reserve position in the IMF, sales of a portion of Treasury’s gold and SDR holdings, as well as by other means. With this war chest—and supported by tighter Federal Reserve monetary policy—the United States began to intervene much more forcefully in the exchange market, often in coordinated operations with other central banks. The decline in the dollar was halted, and after the fundamental change in Federal Reserve operating techniques and the tightening of monetary policy in October 1979, the dollar strengthened, enabling the authorities to intervene on the other side of the market during 1980 and early 1981 to recoup much of the foreign currency that had been used for earlier dollar support.

The second period covered the years from early 1981 to 1985. After the election of President Reagan, the U.S. Administration interpreted the goal of countering disorderly markets very narrowly. The authorities maintained a hands-off approach, and intervention in the exchange market was minimal. During this period, the dollar exchange rate rose strongly, in an environment of a robust U.S. economy, large budget deficits, and a tight monetary policy with interest rates that were very high by international standards.

The third period covered the time from early 1985 until February 1987. The dollar eased somewhat in the spring and summer of 1985, and an important turning point occurred at the meeting of the United States and its major industrial allies in the Group of Five—France, Germany, Japan, and the United Kingdom—at the Plaza Hotel in New York in September 1985. The dollar was still at very high levels that caused concern in the United States and abroad. In the United States there was considerable apprehension about declining U.S. competitiveness and a loss of industrial output to overseas production, and a fear of rising protectionism. Also, there was a widespread belief that the exchange rates of the major currencies against the dollar did not reflect economic fundamentals. Against this background, the finance ministers and central bank governors of
the G-5 reached an agreement that an appreciation of foreign currencies relative to the dollar was desirable. In the weeks following the Plaza meeting, there were substantial intervention sales of dollars for other G-5 currencies by the United States and by other monetary authorities. U.S. intervention sales of dollars were confined to rising markets—on occasions after the dollar eased, the United States moved in to resist market pressures that would otherwise have tended to raise it back to pre-existing higher levels. The dollar declined significantly during 1985 and continued to decline during 1986, even though there was no further U.S. market intervention after the first few weeks following the Plaza agreement.

The fourth period was from February 1987 to the end of that year. By early 1987, eighteen months after the Plaza agreement, the dollar had declined to its lowest levels since 1980. With a growing trade deficit and a weakening U.S. economy, the prospect of further declines in the dollar had become a cause of concern, particularly in Europe and Japan. Six major industrial nations (the Group of Five plus Italy) met at the Louvre in Paris in February and issued a statement that their currencies were “within ranges broadly consistent with underlying economic fundamentals.” They agreed “to foster stability of exchange rates around current levels.” The United States, frequently in coordinated operations with other central banks, intervened on a number of occasions to buy dollars and resist the dollar’s decline. But despite the intervention, the dollar continued to decline irregularly over the remainder of 1987. Many market analysts argued that the dollar’s decline reflected rifts among the major G-7 nations over monetary and fiscal policies. There was concern about the risks of the situation, particularly at the time of the U.S. stock market crash in October. These uncertainties continued until the beginning of 1988, at which time, following visible, concerted, and very aggressive intervention operations by the United States and others, the dollar stabilized and reversed its direction.

In the fifth period, covering 1988 to 1990, the dollar again trended upward, and the United States intervened, at times very heavily, in the interest of exchange rate stability, to resist upward pressure on the dollar. Once again, these operations were undertaken after statements from the Group of Seven (The Group of Five plus Italy and Canada) emphasized the importance of maintaining exchange rate stability. The G-7 issued a statement expressing concern that the continued rise of the dollar was “inconsistent with longer-run fundamentals” and that a further rise of the dollar above then-current levels, or an excessive decline, could adversely affect prospects for the world economy. The level of U.S. intervention operations during 1989 was particularly high by earlier standards, resulting in the accumulation of substantial U.S. reserve balances of foreign currencies, namely Deutsche marks and yen. This was the first time that the United States had held “owned,” or non-borrowed, foreign currency reserves in large amounts.

Since 1990, the general approach has been to allow considerable scope for market forces, with intervention from time to time to resist moves that seem excessive in either direction. The U.S. authorities have on occasion sold dollars when the currency was deemed to be getting “too strong” relative to economic fundamentals and bought when it was regarded as becoming “too weak”—but the occasions have been infrequent. Operations have been modest in amounts, and often undertaken in coordinated operations with other G-7 authorities—in particular, when these other countries were concerned about the mirror image position of their own currencies, and the effect of movements in the dollar exchange rate on their own currencies. There is a recognition of the benefits and the limitations of intervention
(discussed in Chapter 11), and of the situations and policy framework in which it is likely to be most helpful.

During the 1990s, there has been intervention by the U.S. authorities on both sides of the market—that is, buying dollars from time to time to resist downward pressure on the dollar exchange rate and selling dollars on a few occasions of strong upward pressure.

In 1991 and 1992, the U.S. intervened on both sides, buying a total of $2,659 million in dollars and selling a total of $750 million.

From 1993 through mid-1995, market pressures against the dollar were mainly downward, and the U.S. authorities intervened to buy dollars on 18 trading days, with purchases totaling $14 billion, just over half of which were purchased against yen, with the remainder purchased against marks. (For many years, the mark and the yen have been the only two currencies in which the United States has conducted its intervention operations.)

From mid-1995 until mid-1998, there were no dollar intervention operations undertaken by the U.S. authorities.

In mid-1998, the U.S. authorities re-entered the market, in cooperation with the Japanese authorities, to sell dollars for yen in an environment of weakness in the yen exchange rate.

All U.S. intervention operations in the foreign exchange market are publicly reported on a quarterly basis, a few weeks after the close of the period. These reports, entitled “Treasury and Federal Reserve Foreign Exchange Operations,” are presented by the Manager of the System Open Market Account and are published by the Federal Reserve Bank of New York and in the Federal Reserve Bulletin. Each report documents any U.S. intervention activities of the previous quarter, describing the market environment in which they were conducted. This series provides a record of U.S. actions in the foreign exchange market for the period since 1961.

### 3. Executing Official Foreign Exchange Operations

In some countries the central bank serves as the government’s principal banker, or only banker, for international payments. In such cases, the central bank may buy and sell foreign exchange, not only for foreign exchange intervention purposes, but also for such purposes as paying government bills, servicing foreign currency debts, and executing transactions for the national post office, railroads, and power company.

The Federal Reserve Bank of New York conducts all U.S. intervention operations in the foreign exchange market on behalf of the U.S. monetary authorities. It also conducts certain non-intervention business transactions on behalf of various U.S. Government agencies. Given the vast array of international activities in which U.S. Government departments and agencies are involved, it is left to individual agencies to acquire the foreign currencies needed for their operations in the most economical way they can find. Today, only a fraction of the U.S. Government’s total foreign exchange transactions are funneled through the Federal Reserve Bank of New York; the bulk of such transactions go directly through commercial or other channels.
Even so, the Foreign Exchange Desk of the Federal Reserve Bank of New York is routinely engaged in foreign exchange transactions on behalf of “customers.” Thus, when operating in the foreign exchange market, the Desk is not necessarily “intervening” to influence the dollar exchange rate or conditions in the dollar market. It simply may be executing “customer” business. The customer may be another official body, and the Federal Reserve may be either helping a foreign central bank get the best available price for some commercial or financial transaction or helping that central bank (with that bank’s own resources) intervene in its own currency, perhaps when its own market is closed.

There are many central bank correspondents holding dollar balances at the New York Fed, with bills to pay in non-dollar currencies, who find it convenient and economical to obtain their needed currencies through the Fed. Similarly, the New York Fed transacts customer-based foreign exchange business for a number of international institutions that hold dollar balances at the Fed.

But it is the intervention activity—circumstances, amounts, techniques, policy environment surrounding intervention operations, and possible effectiveness of such operations in influencing the exchange rate or market conditions—that is of particular interest and attracts the most attention.

▶ Techniques of Intervention

Techniques of intervention can differ, depending on the objective and market conditions at the time. The intervention may be coordinated with other central banks or undertaken by a single central bank operating alone. The situation may call for an aggressive action, intended to change existing attitudes about the authorities’ views and intentions, or it may call for reassuring action to calm markets. The aim may be to reverse, resist, or support a market trend. Operations may be announced or unannounced. Central banks may operate openly and directly, or through brokers and agents. They may deal with many banks or few, in sudden bursts, or slowly and steadily. They may want the operations to be visible or they may want to operate discreetly. Different objectives may require different approaches.

In the foreign exchange operations undertaken on behalf of the United States authorities, the Federal Reserve Bank of New York has, over the years, used various intervention techniques, depending on the policy objective, market conditions, and an assessment of what appears likely to be effective. In recent years, most U.S. intervention has been conducted openly, directly with a number of commercial banks and other participants in the interbank market, with the expectation that the intervention would be seen very quickly and known by the entire foreign exchange market, both in the United States and abroad. The aim has been to show a presence in the market and indicate a view about exchange rate trends. On recent occasions, there have been accompanying statements by the Secretary of the Treasury or another senior Treasury official announcing or confirming the operations.

At the New York Fed, the Foreign Exchange Desk monitors the foreign exchange market on a continuing basis, watching the market and keeping up-to-date with significant developments that may be affecting the dollar and other major currencies. The Desk staff tracks market conditions around the clock during periods of stress. Federal Reserve staff, like others in the market, sit in a trading room surrounded by screens, telephones, and
The Foreign Exchange Market in the United States

There is no fixed or formal procedure in the United States for reaching decisions on intervention. On occasions there may be a major agreement among the main industrial countries to follow a particular approach—for example, the decisions at the Plaza in 1985 and at the Louvre in 1987 required a coordinated approach toward the exchange market that had major implications for intervention. There may be other occasions, when the U.S. authorities conclude that some action or change in approach is needed, and they may want to discuss intervention informally with other major countries to see whether coordinated action is possible. In still other situations, when either the Treasury or the Federal Reserve believes a change in approach is called for, there will be discussions among senior U.S. officials of that viewpoint. Indeed, there are any number of possible way in which questions of exchange rate policy can by considered.

When the Desk does undertake intervention purchases or sales, the financing is usually split evenly between the Treasury’s Exchange Stabilization Fund and the Fed’s System Open Market Account. However, there are occasions when, for technical or other reasons, the financing for a particular operation is booked entirely by the Treasury or the Federal Reserve.

The dollar amount of any U.S. foreign exchange market intervention is routinely sterilized—that is, the effect on the monetary base, plus or minus, is promptly offset. Indeed, it is generally the practice in most major industrial countries to sterilize intervention operations, at least over a period of time. Thus, any expansion (or contraction) in the monetary base resulting from selling (or buying) dollars in the foreign exchange market would be automatically offset by the Federal Reserve’s domestic monetary actions. While the sterilized foreign exchange market intervention does not itself affect the U.S. money stock, that does not imply that conditions in the foreign exchange market do not influence monetary policy decisions—at times they clearly do. But that influence shows up as a deliberate monetary policy decision, rather than as a side effect of the foreign exchange market intervention.
5. Financing Foreign Exchange Intervention

All foreign exchange operations by the monetary authorities must, of course, be financed. In the case of a foreign central bank operating in dollars to influence the exchange rate for its currency, that simply may mean transfers into or out of its dollar accounts (held at the Federal Reserve Bank of New York or at commercial banks) as it buys and sells dollars in the market. For the United States, it currently means adding to or reducing the foreign currency balances held by the Treasury and the Federal Reserve. However, U.S. techniques for acquiring resources for exchange market operations have gone through several phases.

During the late 1940s and the 1950s, under the Bretton Woods system, the United States kept its reserves almost entirely in the form of gold, and did not hold significant foreign currency balances. Since the U.S. role in the foreign exchange markets was entirely passive, market intervention and financing market intervention were not an issue.

In the early 1960s, when the United States began to operate more actively in the foreign exchange market and was reluctant to draw down its gold stock, the U.S. authorities began the practice of establishing reciprocal currency arrangements—or swap lines—with central banks and other monetary authorities abroad, as a means of gaining rapid access to foreign currencies for market intervention and other purposes.

These reciprocal swap lines were developed as a technique for prearranging short-term credits among central banks and treasuries, enabling them to borrow each other’s currencies—if both sides agreed—at a moment’s notice, in event of need. Over time, a network of these facilities was built up, mainly between the Federal Reserve and the major foreign central banks and the Bank for International Settlements (BIS), although the Treasury also has swap lines. These facilities have enabled the United States to acquire foreign currencies when they were needed for foreign exchange operations, and from time to time some of the swap partners drew on the facilities to obtain dollars they needed for their own market operations.

An advantage of the central bank reciprocal swap lines was that drawings could be activated quickly and easily, in case of mutual consent. A drawing could be initiated by a phone call followed by an exchange of cables in which particular terms and conditions were specified within the standard framework of the swap agreement. Technically, a central bank swap drawing consists of a spot transaction and a forward exchange transaction in the opposite direction. Thus, the Federal Reserve might sell spot dollars for, say marks, to the German central bank, and simultaneously contract to buy back the same amount of dollars three months later. By mutual agreement, the drawing might be rolled over for additional three-month periods.

Central bank swap lines were used actively by the United States in periods of exchange market pressure during the 1960s and 1970s, when the United States did not hold substantial foreign currency balances. They had important advantages, but also some limitations. To be activated, swap drawings required the consent of both parties. They did not provide foreign currencies to the borrower unless the partner central bank agreed. As with any credit, availability can be made subject to policy or other conditions imposed by the creditor that the borrower might not like. Also, swap drawings were technically short term, requiring agreement every three months for a rollover.
In November 1978, when the U.S. authorities wanted to correct what was regarded as an excessive decline in the dollar’s value in the exchange market, they decided to increase by a substantial amount their “owned reserves,” or foreign currency balances fully available to them and under their own control, and not be restricted to “borrowed reserves,” or balances available from, and limited by, swap arrangements. The U.S. authorities wanted to show their determination to support and strengthen the dollar by taking new, innovative, and unprecedented actions, and by building up a large supply of foreign currencies that could be used by the United States at its sole discretion for aggressive intervention.

Accordingly, to increase its “owned reserves,” the United States Treasury announced that it would draw $3 billion worth of marks and yen from the U.S. reserve position in the IMF; that it would sell $2 billion equivalent of IMF Special Drawing Rights (SDR) for marks, yen, and Swiss francs; and, as a major innovation, that it would, for the first time, borrow foreign currencies in overseas markets. The U.S. Treasury was prepared to issue foreign currency-denominated securities up to the equivalent of $10 billion.

Between November 1978 and January 1981, foreign currency-denominated securities (called Carter bonds) were issued amounting to the equivalent of approximately $6.5 billion, all in German marks and Swiss francs. All of these securities were redeemed by mid-1983. The dollar strengthened during the period when the securities were outstanding, and the Treasury made a profit on the amounts of borrowed currencies that were used for intervention when the dollar was low and bought back when the dollar was higher. In the early 1980s, the United States was able to move to a modest net positive foreign currency position, with foreign currency balances somewhat in excess of its foreign currency liabilities.

The next important change in this situation occurred in the late 1980s, when the U.S. authorities built up their foreign currency balances to far higher levels than ever before. During periods of strong upward pressure on the dollar exchange rate, the United States intervened in substantial amounts to resist what was regarded as excessive upward pressure on the dollar, and acquired substantial balances of marks and yen. As of the middle of 1988, the United States held foreign currency balances of only $10 billion. But by the end of 1990, the United States reported foreign currency balances of more than $50 billion. Since then, there has been some net use of these balances for intervention purposes, and some reduction through exchanges of U.S. foreign currency balances for dollars with the issuers of those currencies, when both parties felt they were holding excess amounts relative to their needs. In June 1998, the U.S. authorities held $30 billion in marks and yen; these balances are marked-to-market on a monthly basis. U.S. holdings of international reserves (excluding gold), measured relative to imports or size of the economy, still remain well below the levels of many other major industrial nations.

The reciprocal currency arrangements, or swap lines, remain in place, and are available if needed. At present, the Federal Reserve has such arrangements with 14 foreign central banks and the Bank for International Settlements, totaling $32.4 billion (Figure 9-1). For many years, however, the United States has not drawn on any of the swap lines for financing U.S. intervention or for any other purpose. There have been drawings on both Federal Reserve and Treasury ESF swap facilities initiated by the other party to the swap—in particular, swap lines have
providing temporary financing in dealing with the Mexican financial crisis and certain earlier Latin American debt problems.

The foreign currency balances owned by the Treasury’s Exchange Stabilization Fund and by the Federal Reserve System are regularly invested in a variety of instruments that have a high degree of liquidity, good credit quality, and market-related rates of return. A significant portion of the balances consists of German and Japanese government securities, held either directly or under repurchase agreement. As of June 1998, outright holdings of foreign government securities by U.S. monetary authorities totaled $7.1 billion, and government securities held under repurchase agreements by U.S. monetary authorities totaled $10.9 billion. The Federal Reserve Bank of New York makes these various investments for both the Treasury and the Federal Reserve, and the Desk stays in close contact with German and Japanese money market and capital market sources in arranging these transactions.
1. Estimates of dealer turnover in “non-traditional” OTC products and in exchange-traded products are not reported in the same way as the “traditional” OTC products, and it is difficult to compare the two in a meaningful way.

3. As noted in Chapter 8, one of the approaches being explored for dealing with “settlement risk”—the risk that one bank pays out currency to settle a trade, but the counterparty bank does not pay out the other currency—is netting +, a technique for rolling settlement forward from day to day by using tom-next swaps.

5. For example, on July 1, two netting + counterparties determine that on July 2, Party A owes CHF 300 million (Swiss francs) to Party B, and B owes $200 million to A. Under netting +, a tom-next swap would be executed under which A buys CHF 300 million from B for value July 2 and sells CHF 300 million to B for value July 3, at current market rates. The CHF cash flows for July 2 are thus netted down to zero (no CHF delivery) and the residual U.S. dollar cash flow remains to be paid by one party to the other. (Thus, if the July 2 leg of the tom-next swap was done at $1 = CHF 1.5152, i.e. for $198 million, B would pay A $2 million.) Payments related to the “next” part of the tom-next swap would be combined with other cash flows due July 3, which, in turn, would be offset by a new tom-next swap, and so on. (New York Foreign Exchange Committee, *Guidelines for Foreign Exchange Settlement Netting*.)
